Abstract

The bundle structure of the space $\overline{\mathcal{A}}$ of Ashtekar's generalized connections is investigated in the compact case. It is proven that every stratum is a locally trivial fibre bundle. The only stratum being a principal fibre bundle is the generic stratum. Its structure group equals the space $\overline{\mathcal{G}}$ of all generalized gauge transforms modulo the constant center-valued gauge transforms. For abelian gauge theories the generic stratum is globally trivial and equals the total space $\overline{\mathcal{A}}$. However, for a certain class of non-abelian gauge theories – e.g., all $SU(N)$ theories – the generic stratum is nontrivial. This means, there are no global gauge fixings – the so-called Gribov problem. Nevertheless, there is a covering of the generic stratum by trivializations each having total induced Haar measure 1.

1 Introduction

The functional integral approach to quantum field theories consists of two basic steps: first the determination of a “physical” (Euclidian) measure on the configuration space and second the reconstruction of the quantum theory via an Osterwalder-Schrader procedure. In this paper we will focus on a certain issue arising in the first step – the Gribov problem.

The configuration space of smooth gauge field theories has a very complicated structure. The space $\mathcal{A}/\mathcal{G}$ of all smooth gauge orbits is, in general, neither affine, nor compact, nor a manifold. In contrast, the space $\mathcal{A}$ of all smooth gauge fields (mathematically, connections) is an affine space, and therefore (from the mathematical point of view) by far more pleasant. That is why in the 60s Faddeev and Popov [11] proposed the following strategy for the gauge-invariant formulation of functional integrals: First one defines on $\mathcal{A}$ the formal measure $\mathcal{D}A = \prod_{x,\mu} dA^\mu(x)$. Due to the gauge invariance of the Yang-Mills action S_{YM} the functional integral $\int e^{iS_{\text{YM}}(A)} \mathcal{D}A$ has to be naively proportional to the integral $\int \mathcal{D}g \equiv \int \prod_x dg(x)$ over all gauge transforms. In order to separate this unphysical factor, one chooses a gauge fixing, e.g. (as Faddeev and Popov did) $\partial_\nu A^\nu = 0$, and gets $\prod_{x,\mu} dA_\mu(x) = \Delta(A) \prod_x \left(\delta(\partial_\nu A^\nu(x)) \prod_\mu dA^\mu(x) \right) \prod_x dg(x)$. The so called Faddeev-Popov determinant $\Delta(A)$, a kind of a degenerate Jacobi determinant, has now to be chosen such that $\Delta(A) \prod_x \delta(\partial_\nu (A \circ g)^\nu(x)) dg(x)$ becomes a constant independent of A . Finally, $\prod_x \left(\delta(\partial_\nu A^\nu(x)) \prod_\mu dA^\mu(x) \right)$ is to be considered as an equivalent of a measure on $\mathcal{A}/\mathcal{G}$.

About ten years later, Gribov [15] noticed a severe problem: The Coulomb gauge is (for certain gauge theories) *no* gauge fixing since in some gauge orbits several connections fulfill the gauge condition. Therefore, besides the Faddeev-Popov determinant a corresponding, highly nontrivial factor had to be inserted into the functional integral. Now, one was hoping to avoid this problem using another gauge fixing. But this hope broke down a few months later: Singer [27] investigated this problem more systematically and found that the non-existence of gauge fixings is a typical property of gauge theories with non-compact structure group. Mathematically, this means simply that there is *no* global section in the foliation $\mathcal{A} \longrightarrow \mathcal{A}/\mathcal{G}$ of the set of connections over the gauge orbit space. Moreover, Singer was able to prove that (for structure group $\mathbf{G} = SU(N)$ and spacetime manifold $M = S^4$) there is no global section even in the principal fibre bundle of all irreducible connections.

Most of these problems can be formulated and could arise in a similar way also in the Ashtekar framework which differs (in the gauge-theoretical sense) from the standard one mainly in the usage of distributional connections instead of only smooth ones. Therefore we want to study in the present paper whether there is a Gribov problem for Ashtekar connections as well and, if necessary, study its impact. Our considerations can be understood as a continuation of the investigations started in [13, 12] on the structure of the configuration space of generalized gauge theories.

1.1 Preliminaries

Before we outline the paper we recall the basic facts and notations from [13] where the details can be found. Other references are [1, 2, 3].

Let the “space-time” M be an at least two-dimensional manifold, $m \in M$ some fixed point and the structure group $\mathbf{G}$ be a compact and (for technical reasons) connected Lie group. $\mathcal{P}$

denotes the groupoid of all paths in M , $\mathcal{HG}$ the group of all paths starting and ending in m . The set $\overline{\mathcal{A}}$ of generalized connections $\overline{A}$ is defined by $\overline{\mathcal{A}} := \varprojlim_{\Gamma} \mathbf{G}^{\#\mathbf{E}(\Gamma)} = \text{Hom}(\mathcal{P}, \mathbf{G})$. Here Γ runs over all finite graphs in M . $\mathbf{E}(\Gamma)$ is the set of edges in Γ , $\mathbf{V}(\Gamma)$ will be that of all vertices. The set $\overline{\mathcal{G}}$ of generalized gauge transforms $\overline{g}$ is $\overline{\mathcal{G}} := \varprojlim_{\Gamma} \mathbf{G}^{\#\mathbf{V}(\Gamma)} = \text{Maps}(M, \mathbf{G})$. It acts continuously on $\overline{\mathcal{A}}$ via $h_{\overline{A} \circ \overline{g}}(\gamma) = g_{\gamma(0)}^{-1} h_{\overline{A}}(\gamma) g_{\gamma(1)}$ where the path γ is in $\mathcal{P}$ and $h_{\overline{A}}$ is the homomorphism corresponding to $\overline{A}$. The stabilizer $\mathbf{B}(\overline{A})$ of $\overline{A}$ contains exactly those gauge transforms that fulfill $h_{\overline{A}}(\gamma_x) = g_m^{-1} h_{\overline{A}}(\gamma_x) g_x$ for all $x \in M$ and whose m -component g_m lies in the holonomy centralizer $Z(\mathbf{H}_{\overline{A}})$ of $\overline{A}$, i.e. the centralizer of the holonomy group of $\overline{A}$. Here, for all x , γ_x is some fixed path from m to x . We have $\mathbf{B}(\overline{A}) \cong Z(\mathbf{H}_{\overline{A}})$. Now, the orbit type of $\overline{A}$ is defined to be the $\overline{\mathcal{G}}$ -conjugacy class of $\mathbf{B}(\overline{A})$, but equivalently it can be defined to be the $\mathbf{G}$ -conjugacy class $[Z(\mathbf{H}_{\overline{A}})]$ of the holonomy centralizer of $\overline{A}$. This definition will be used in the following. The types are partially ordered by the natural inclusion-induced ordering of classes of subgroups of $\mathbf{G}$. A stratum $\overline{\mathcal{A}}_t$ is the set of all connections $\overline{A} \in \overline{\mathcal{A}}$ having type t and the generic stratum $\overline{\mathcal{A}}_{\text{gen}}$ is the set of all connections having the maximal orbit type $[Z]$ where $Z \equiv Z(\mathbf{G})$ is the center of $\mathbf{G}$. $\overline{\mathcal{A}}_{\text{gen}}$ is an open, dense and $\overline{\mathcal{G}}$ -invariant subset of $\overline{\mathcal{A}}$. Furthermore, there is a slice theorem on $\overline{\mathcal{A}}$. This means, for every $\overline{A} \in \overline{\mathcal{A}}$ there is a so-called slice $\overline{\mathcal{S}} \subseteq \overline{\mathcal{A}}$ with $\overline{A} \in \overline{\mathcal{S}}$ such that:

- $\overline{\mathcal{S}} \circ \overline{\mathcal{G}}$ is an open neighbourhood of $\overline{A} \circ \overline{\mathcal{G}}$ and
- there is an equivariant retraction $F : \overline{\mathcal{S}} \circ \overline{\mathcal{G}} \longrightarrow \overline{A} \circ \overline{\mathcal{G}}$ with $F^{-1}(\{\overline{A}\}) = \overline{\mathcal{S}}$.

The most important tool for the proof of this theorem has been a so-called reduction mapping φ_{α} . Note, due to the compactness of $\mathbf{G}$, any centralizer is finitely generated and consequently there is a finite set $\alpha \subseteq \mathcal{HG}$ of paths starting and ending in m such that $Z(h_{\overline{A}}(\alpha)) = Z(\mathbf{H}_{\overline{A}})$. Since $Z(h_{\overline{A}}(\alpha))$ is the orbit type of $h_{\overline{A}}(\alpha)$ w.r.t. the adjoint action of $\mathbf{G}$ on $\mathbf{G}^{\#\alpha}$, the reduction mapping $\varphi_{\alpha} : \overline{\mathcal{A}} \longrightarrow \mathbf{G}^{\#\alpha}$ with $\overline{A}' \mapsto h_{\overline{A}'}(\alpha)$ lifts the slice theorem from $\mathbf{G}^{\#\alpha}$ to $\overline{\mathcal{A}}$. The notion of a reduction mapping will be crucial again in the present paper.

Finally we note that there is a natural measure μ_0 on $\overline{\mathcal{A}}$, the so-called Ashtekar-Lewandowski measure or induced Haar measure [12, 2]. At the moment, we should only notice that $\mu_0(\pi_{\Gamma}^{-1}(U)) = \mu_{\text{Haar}}(U)$ for all graphs Γ with corresponding projections $\pi_{\Gamma} : \overline{\mathcal{A}} \longrightarrow \mathbf{G}^{\#\mathbf{E}(\Gamma)}$, $\pi_{\Gamma}(\overline{A}) = (h_{\overline{A}}(e_1), \dots, h_{\overline{A}}(e_{\#\mathbf{E}(\Gamma)}))$, and all measurable $U \subseteq \mathbf{G}^{\#\mathbf{E}(\Gamma)}$.

1.2 Outline of the Paper

The guideline for our paper will be given by the following five questions.

Question 1 Is $\pi : \overline{\mathcal{A}} \longrightarrow \overline{\mathcal{A}}/\overline{\mathcal{G}}$ a fibre bundle?

In general, the answer is negative; at least, if we demand, that all fibres $\overline{A} \circ \overline{\mathcal{G}}$ have to be isomorphic $\overline{\mathcal{G}}$ -spaces. This required [6] that all stabilizers are $\overline{\mathcal{G}}$ -conjugate. But, this implies [13] that all Howe subgroups of $\mathbf{G}$ have to be $\mathbf{G}$ -conjugate. This, however, is only possible for abelian $\mathbf{G}$.

For arbitrary $\mathbf{G}$ we can expect bundle structures only on subsets of $\overline{\mathcal{A}}$ where all connections have conjugate stabilizers. The maximal sets of that kind are exactly the sets of connections having one and the same gauge orbit type t , i.e. the strata $\overline{\mathcal{A}}_t$.

Question 2 Are the strata $\pi : \overline{\mathcal{A}}_t \longrightarrow \overline{\mathcal{A}}_t/\overline{\mathcal{G}}$ locally trivial fibre bundles?

It is well-known that for actions of compact Lie groups on arbitrary (completely regular) spaces the strata are always fibre bundles. However, the proof of this theorem does not

require the Lie property of the acting group, but the existence of a slice theorem. In contrast to the former one the latter one is guaranteed also in our case of interest [13]. Hence, we will be able to prove that the strata are indeed fibre bundles.

The next stronger question is

Question 3 What strata are principal fibre bundles?

For a fibre bundle to be a principal fibre bundle, at least the structure group of that bundle has to equal the typical fibre. Since a stratum $\overline{\mathcal{A}}_{=t}$ has (for general reasons) the typical fibre $\mathbf{B}(\overline{\mathcal{A}}) \setminus \overline{\mathcal{G}}$ and structure group $\mathbf{B}(\overline{\mathcal{A}}) \setminus N(\mathbf{B}(\overline{\mathcal{A}}))$ (for some $\overline{\mathcal{A}} \in \overline{\mathcal{A}}_{=t}$, the stabilizer $\mathbf{B}(\overline{\mathcal{A}})$ has to be a normal subgroup in $\overline{\mathcal{G}}$. (Here, $N(\mathbf{B}(\overline{\mathcal{A}}))$ denotes the normalizer of $\mathbf{B}(\overline{\mathcal{A}})$ w.r.t. $\overline{\mathcal{G}}$.) We will show that this is the case in the generic stratum only.

As every other stratum, the generic stratum is locally trivial.

Question 4 Is $\pi : \overline{\mathcal{A}}_{\text{gen}} \longrightarrow \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$ even globally trivial?

For smooth connections – as mentioned above – this is not the case; this is just the Gribov problem.

In the case of generalized connections the reduction mapping will play again the most important rôle. By its means we can reduce the problem of the triviality of the generic stratum in $\overline{\mathcal{A}}$ to the corresponding problem for the generic stratum in $\mathbf{G}^k$, i.e. the set of all $\vec{g} \in \mathbf{G}^k$ with $Z(\vec{g}) = Z(\mathbf{G})$. Namely, by the finiteness lemma for centralizers [13] we find finitely many $g_i \in \mathbf{G}$ with $Z(\vec{g}) \equiv Z(\{g_1, \dots, g_k\}) = Z(\mathbf{G})$. Now we choose a graph Γ having k edges $\alpha_i \in \mathcal{HG}$ and one vertex m and denote the corresponding reduction mapping $\pi_\Gamma : \overline{\mathcal{A}} \longrightarrow \mathbf{G}^k$ simply by φ . Since φ is surjective even on $\overline{\mathcal{A}}_{\text{gen}}$ [13], we get the following commutative diagram

$$\begin{array}{ccc} \overline{\mathcal{A}}_{\text{gen}} & \xrightarrow{\varphi} & \mathbf{G}^k \\ \downarrow \pi & & \downarrow \pi_k \\ \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}} & \xrightarrow{[\varphi]} & \mathbf{G}^k/\text{Ad} \end{array} .$$

One could now conjecture that the generic stratum should be nontrivial because otherwise one would get a trivialization of $\pi_k : \mathbf{G}^k \longrightarrow \mathbf{G}^k/\text{Ad}$, although in general π_k is not a fibre bundle. However, this argumentation is incorrect; namely, there is no “gauge invariant” section for φ , i.e. no induced section for $[\varphi]$. But, restricting $\mathbf{G}^k$ in the diagram above to the generic elements (and modify the remaining three spaces accordingly to the given maps) this obstruction disappears. Indeed, we will be able to prove that $\pi : \overline{\mathcal{A}}_{\text{gen}} \longrightarrow \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$ is nontrivial, as far as $\pi_k : (\mathbf{G}^k)_{\text{gen}} \longrightarrow (\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ is nontrivial. Moreover, we will explicitly determine a couple of groups (among them $\mathbf{G} = SU(N)$) that fulfill the criterion. Hence we will prove that the Gribov problem appears for generalized connections again.

In the case of continuous connections the impact of the Gribov problem to the calculation of functional integrals is enormous. Since for the integration trivial subbundles are of special interest, we have the next natural

Question 5 What “size” can trivial subbundles of $\overline{\mathcal{A}}_{\text{gen}}$ have at most?

Using the reduction mapping above we can show that the triviality of π_k over $V \subseteq (\mathbf{G}^k)_{\text{gen}}$ implies the triviality of π over $\varphi^{-1}(V) \subseteq \overline{\mathcal{A}}_{\text{gen}}$. Consequently we get as a by-product that π is trivial on the whole $\overline{\mathcal{A}}_{\text{gen}} \equiv \overline{\mathcal{A}}$ for abelian $\mathbf{G}$. In the general case our task will be the search for domains where π_k is trivial. The idea for that comes from the fact that a smooth principal fibre bundle over a contractible manifold is always trivial. Hence we triangulate $(\mathbf{G}^k)_{\text{gen}}/\text{Ad}$, cut out the lower-dimensional simplices (this is in particular a set of [Lebesgue] measure 0) and get a disjoint union W of contractible manifolds. The preimage of that union by $\pi_k \circ \varphi$ yields the desired trivialization $U \subseteq \overline{\mathcal{A}}_{\text{gen}}$ with $\mu_0(U) = \mu_{\text{Haar}}(\pi_k^{-1}(W)) = 1$.

This way we have found a trivial subbundle arisen from $\overline{\mathcal{A}}$ by cutting out certain zero subsets. This means that for generalized connections the Gribov problem is completely irrelevant for the calculation of functional integrals supposed the considered measure on $\overline{\mathcal{A}}$ is absolutely continuous w.r.t. the induced Haar measure.

Up to this limitation we get for generalized connections:

The Gribov problem appears, but it causes no longer a problem.

In this paper we investigate first the fibre bundle structure of the strata and prove that the generic stratum is the only stratum having the structure of a principal fibre bundle. Next, we show that $\mathbf{G}^k$ for sufficiently large k is globally trivial up to a zero subset and transfer this statement to $\overline{\mathcal{A}}$. The proof is quite technical, although its idea sketched above is rather simple. Then we prove the triviality of $\overline{\mathcal{A}}$ in the abelian case. Finally, we state a group-theoretical criterion for the nontriviality of $\overline{\mathcal{A}}_{\text{gen}}$ in the nonabelian case and discuss which concrete $\mathbf{G}$ fulfill this criterion. The example $\mathbf{G} = SU(2)$ will be described in Appendix B in detail.

2 Fibre Bundle Structure of the Strata

Proposition 2.1 Let $t \in \mathcal{T}$ be a gauge orbit type and $\overline{A} \in \overline{\mathcal{A}}_{=t}$ be some connection of that type.

Then the stratum $\overline{\mathcal{A}}_{=t}$ is a locally trivial fibre bundle over $\overline{\mathcal{A}}_{=t}/\overline{\mathcal{G}}$ with fibre $\mathbf{B}(\overline{A}) \setminus \overline{\mathcal{G}}$ and structure group $\mathbf{B}(\overline{A}) \setminus N(\mathbf{B}(\overline{A}))$ acting on the typical fibre by left translation.

Proof We know from [13] that there is a slice theorem on $\overline{\mathcal{A}}$. Now the assertion follows immediately because in general every stratum of a space with slice theorem is such a fibre bundle (cf. Appendix D). **qed**

Remark The preceding proposition is a further generalization of a result for regular connections to the Ashtekar approach. Already in 1978, Daniel and Viallet [8] noticed that classically gauge fixings always exist at least locally. This result was confirmed by the later statements [25, 23, 20, 21] on the triviality of the strata.

We know already from [13] that a lot of structures in $\overline{\mathcal{G}}$ can be reduced to structures in the Lie group $\mathbf{G}$. For instance, we have seen that $\mathbf{B}(\overline{A})$ is always isomorphic to $Z(\mathbf{H}_{\overline{A}})$. This, the other way round, implies that the homeomorphy class of each orbit is determined not only by $\mathbf{B}(\overline{A}) \setminus \overline{\mathcal{G}}$, but also by $Z(\mathbf{H}_{\overline{A}}) \setminus \mathbf{G}$. We will see now that there is an analogous result for the structure group $\mathbf{B}(\overline{A}) \setminus N(\mathbf{B}(\overline{A}))$. We start investigating $N(\mathbf{B}(\overline{A}))$ itself.

Proposition 2.2 Let $\bar{A} \in \bar{\mathcal{A}}$ and $\bar{g} \in \bar{\mathcal{G}}$. Furthermore, we again fix for every $x \in M$ a path γ_x from m to x , where γ_m is trivial. Then we have $\bar{g} \in N(\mathbf{B}(\bar{A}))$ iff

1. $g_m \in N(Z(\mathbf{H}_{\bar{A}}))$ and
2. $g_x \in h_{\bar{A}}(\gamma_x)^{-1} Z(Z(\mathbf{H}_{\bar{A}})) g_m h_{\bar{A}}(\gamma_x)$ for all $x \in M$.

Proof In general, $\bar{g} \in N(\mathbf{B}(\bar{A})) \iff \bar{g}^{-1} \mathbf{B}(\bar{A}) \bar{g} \subseteq \mathbf{B}(\bar{A})$.
So let $\bar{g} \in \bar{\mathcal{G}}$ and $\bar{g}' \in \mathbf{B}(\bar{A})$. Then we have

$$\begin{aligned}
& \bar{g}^{-1} \bar{g}' \bar{g} \in \mathbf{B}(\bar{A}) \\
\iff & \begin{aligned} & 1. \quad g_m^{-1} g'_m g_m \in Z(\mathbf{H}_{\bar{A}}) \\ & 2. \quad h_{\bar{A}}(\gamma_x) = (g_m^{-1} g'_m g_m)^{-1} h_{\bar{A}}(\gamma_x) (g_x^{-1} g'_x g_x) \quad \forall x \in M \end{aligned} \\
\iff & \begin{aligned} & 1. \quad g_m^{-1} g'_m g_m \in Z(\mathbf{H}_{\bar{A}}) \\ & 2. \quad g_m h_{\bar{A}}(\gamma_x) g_x^{-1} h_{\bar{A}}(\gamma_x)^{-1} = (g'_m)^{-1} g_m h_{\bar{A}}(\gamma_x) g_x^{-1} h_{\bar{A}}(\gamma_x)^{-1} g'_m \quad \forall x \in M. \\ & \quad \quad \quad (\text{since } g'_x = h_{\bar{A}}(\gamma_x)^{-1} g'_m h_{\bar{A}}(\gamma_x)) \end{aligned}
\end{aligned}$$

Hence,

$$\begin{aligned}
& \bar{g} \in N(\mathbf{B}(\bar{A})) \\
\iff & \bar{g}^{-1} \bar{g}' \bar{g} \in \mathbf{B}(\bar{A}) \quad \forall \bar{g}' \in \mathbf{B}(\bar{A}) \\
\iff & \begin{aligned} & 1. \quad g_m \in N(Z(\mathbf{H}_{\bar{A}})) \\ & 2. \quad g_m h_{\bar{A}}(\gamma_x) g_x^{-1} h_{\bar{A}}(\gamma_x)^{-1} \in Z(Z(\mathbf{H}_{\bar{A}})) \quad \forall x \in M \end{aligned} \\
\iff & \begin{aligned} & 1. \quad g_m \in N(Z(\mathbf{H}_{\bar{A}})) \\ & 2. \quad g_x \in h_{\bar{A}}(\gamma_x)^{-1} Z(Z(\mathbf{H}_{\bar{A}})) g_m h_{\bar{A}}(\gamma_x) \quad \forall x \in M. \end{aligned}
\end{aligned}$$

qed

Example 1 In the generic stratum we have $Z(\mathbf{H}_{\bar{A}}) = Z(\mathbf{G})$, hence $N(Z(\mathbf{H}_{\bar{A}})) = \mathbf{G}$ and $Z(Z(\mathbf{H}_{\bar{A}})) = \mathbf{G}$. Consequently, $N(\mathbf{B}(\bar{A})) = \bar{\mathcal{G}}$.

Example 2 In the minimal stratum we have $Z(\mathbf{H}_{\bar{A}}) = \mathbf{G}$. Hence $N(Z(\mathbf{H}_{\bar{A}})) = \mathbf{G}$ and $Z(Z(\mathbf{H}_{\bar{A}})) = Z(\mathbf{G})$. By the proposition above we have $\bar{g} \in N(\mathbf{B}(\bar{A}))$ iff there is some $g_m \in \mathbf{G}$ such that $g_x \in h_{\bar{A}}(\gamma_x)^{-1} Z(\mathbf{G}) g_m h_{\bar{A}}(\gamma_x) = Z(\mathbf{G}) h_{\bar{A}}(\gamma_x)^{-1} g_m h_{\bar{A}}(\gamma_x)$ for all $x \in M$.

Remark We realize already at this point that (for nonabelian $\mathbf{G}$) $\mathbf{B}(\bar{A})$ is not a normal subset in $\bar{\mathcal{G}}$ provided $\bar{A}$ has minimal type. A more general statement can be found in Section 4.

The preceding proposition shows how the normalizer of $\mathbf{B}(\bar{A})$ is determined by objects in the Lie group $\mathbf{G}$.

Corollary 2.3 For all $\bar{A} \in \bar{\mathcal{A}}$ the spaces $N(\mathbf{B}(\bar{A}))$ and $N(Z(\mathbf{H}_{\bar{A}})) \times \prod_{x \neq m} Z(Z(\mathbf{H}_{\bar{A}}))$ are homeomorphic.

Proof We see immediately that the map $\Psi_1 : \bar{g} \mapsto (g_m, (h_{\bar{A}}(\gamma_x) g_x h_{\bar{A}}(\gamma_x)^{-1} g_m^{-1})_{x \neq m})$ is a homeomorphism between these two spaces. qed

We emphasize that both subgroups of $\bar{\mathcal{G}}$ are in general *not* isomorphic as topological groups. At least there is no “reasonable” homomorphism. We will discuss this problem a bit more

in detail in Appendix A. Roughly speaking, the homomorphism property is destroyed by the above restriction on g_x to be a (usually non-commutative) product of g_m with elements in $Z(Z(\mathbf{H}_{\bar{A}}))$.

In order to investigate the structure of $\mathbf{B}(\bar{A}) \setminus N(\mathbf{B}(\bar{A}))$, we recall the form of $\mathbf{B}(\bar{A})$. By [13] $\mathbf{B}(\bar{A})$ and $Z(\mathbf{H}_{\bar{A}}) \times \bigtimes_{x \neq m} \{e_{\mathbf{G}}\}$ are isomorphic topological groups. Hence, heuristically

$$\mathbf{B}(\bar{A}) \setminus N(\mathbf{B}(\bar{A})) \quad \text{and} \quad Z(\mathbf{H}_{\bar{A}}) \setminus N(Z(\mathbf{H}_{\bar{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\bar{A}}))$$

are homeomorphic. The group isomorphism, however, is not to be expected: Since the base centralizer $\mathbf{B}(\bar{A})$ and the holonomy centralizer $Z(\mathbf{H}_{\bar{A}})$ are isomorphic groups, it is unlikely that there arise isomorphic groups from originally non-isomorphic groups by factorization. Indeed there are examples (generic connections for $\mathbf{G} = SU(2)$) admitting no such “reasonable” group isomorphism. We will discuss this further in Appendix A.

Proposition 2.4 For every $\bar{A} \in \bar{\mathcal{A}}$

$$\begin{aligned} [\Psi_1] : \mathbf{B}(\bar{A}) \setminus N(\mathbf{B}(\bar{A})) &\longrightarrow Z(\mathbf{H}_{\bar{A}}) \setminus N(Z(\mathbf{H}_{\bar{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\bar{A}})) \\ [\bar{g}]_{\mathbf{B}(\bar{A})} &\longmapsto ([g_m]_{Z(\mathbf{H}_{\bar{A}})}, (h_{\bar{A}}^{-1}(\gamma_x) g_x h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_m^{-1})_{x \neq m}) \end{aligned}$$

is a homeomorphism.

Proof • $[\Psi_1]$ is well-defined.

Let $[\bar{g}_1]_{\mathbf{B}(\bar{A})} = [\bar{g}_2]_{\mathbf{B}(\bar{A})}$, i.e. $\bar{g}_1 = \bar{g}' \bar{g}_2$ with $\bar{g}' \in \mathbf{B}(\bar{A})$. Then $g'_m \in Z(\mathbf{H}_{\bar{A}})$, hence $[g_{1,m}]_{Z(\mathbf{H}_{\bar{A}})} = [g'_m g_{2,m}]_{Z(\mathbf{H}_{\bar{A}})} = [g_{2,m}]_{Z(\mathbf{H}_{\bar{A}})}$. Moreover,

$$\begin{aligned} h_{\bar{A}}^{-1}(\gamma_x) g_{1,x} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{1,m}^{-1} &= h_{\bar{A}}^{-1}(\gamma_x) g'_x g_{2,x} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{2,m}^{-1} (g'_m)^{-1} \\ &= h_{\bar{A}}^{-1}(\gamma_x) g'_x h_{\bar{A}}^{-1}(\gamma_x)^{-1} h_{\bar{A}}^{-1}(\gamma_x) g_{2,x} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{2,m}^{-1} (g'_m)^{-1} \\ &= g'_m h_{\bar{A}}^{-1}(\gamma_x) g_{2,x} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{2,m}^{-1} (g'_m)^{-1} \\ &= h_{\bar{A}}^{-1}(\gamma_x) g_{2,x} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{2,m}^{-1} \end{aligned}$$

due to the properties of $\bar{g}' \in \mathbf{B}(\bar{A})$ [13] and $\bar{g}_i \in N(\mathbf{B}(\bar{A}))$.

- $[\Psi_1]$ is surjective and continuous.

Follows immediately from the commutative diagram

$$\begin{array}{ccc} N(\mathbf{B}(\bar{A})) & \xrightarrow[\cong]{\Psi_1} & N(Z(\mathbf{H}_{\bar{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\bar{A}})) \\ \downarrow & & \downarrow \\ \mathbf{B}(\bar{A}) \setminus N(\mathbf{B}(\bar{A})) & \xrightarrow{[\Psi_1]} & Z(\mathbf{H}_{\bar{A}}) \setminus N(Z(\mathbf{H}_{\bar{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\bar{A}})) \end{array}$$

and Corollary 2.3.

- $[\Psi_1]$ is injective.

Let $[\Psi_1]([\bar{g}_1]) = [\Psi_1]([\bar{g}_2])$. Then $g_{1,m} g_{2,m}^{-1} \in Z(\mathbf{H}_{\bar{A}})$ and

$$h_{\bar{A}}^{-1}(\gamma_x) g_{2,x} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{2,m}^{-1} = h_{\bar{A}}^{-1}(\gamma_x) g_{1,x} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{1,m}^{-1}.$$

This implies

$$\begin{aligned} g_{2,m} h_{\bar{A}}^{-1}(\gamma_x) g_{2,x}^{-1} &= g_{1,m} h_{\bar{A}}^{-1}(\gamma_x) g_{1,x}^{-1} \\ &= g_{1,m} g_{2,m}^{-1} g_{2,m} h_{\bar{A}}^{-1}(\gamma_x) g_{2,x}^{-1} h_{\bar{A}}^{-1}(\gamma_x)^{-1} h_{\bar{A}}^{-1}(\gamma_x) g_{2,x} g_{1,x}^{-1} \\ &= g_{2,m} h_{\bar{A}}^{-1}(\gamma_x) g_{2,x}^{-1} h_{\bar{A}}^{-1}(\gamma_x)^{-1} g_{1,m} g_{2,m}^{-1} h_{\bar{A}}^{-1}(\gamma_x) g_{2,x} g_{1,x}^{-1} \end{aligned}$$

using $\bar{g}_2 \in N(\mathbf{B}(\bar{A}))$ and $g_{1,m} g_{2,m}^{-1} \in Z(\mathbf{H}_{\bar{A}})$. Consequently,

$$h_{\bar{A}}^{-1}(\gamma_x) = (g_{1,m} g_{2,m}^{-1})^{-1} h_{\bar{A}}^{-1}(\gamma_x) g_{1,x} g_{2,x}^{-1},$$

thus $\bar{g}_1 \bar{g}_2^{-1} \in \mathbf{B}(\bar{A})$.

- $[\Psi_1]$ is a homeomorphism.
 $N(\mathbf{B}(\overline{A}))$ is a closed subgroup of $\overline{\mathcal{G}}$, hence compact. Thus, $\mathbf{B}(\overline{A}) \setminus N(\mathbf{B}(\overline{A}))$ is compact as well, hence $[\Psi_1]$ is a continuous map of a compact space to a Hausdorff space. This gives [19] the assertion. **qed**

3 Modified Principal Fibre Bundles

Now we will find out which strata are even principal fibre bundles. Here we will use a slightly modified definition for principal fibre bundles. Actually, one makes the demand on such a bundle that the structure group acts freely on the fibres, i.e. all stabilizers are to be trivial. This will not be the case for generalized connections in general because every holonomy centralizer – being isomorphic to the corresponding stabilizer – contains at least the center of $\mathbf{G}$. Therefore we will factor out exactly these “bugging” parts:

Definition 3.1 A G -space X is called **principal G -fibre bundle** iff all $x \in X$ have the same stabilizer S .

The **structure group** of π is $S \setminus G$.

Sometimes we say that also $\pi : X \longrightarrow X/G$ is a principal G -fibre bundle.

Proposition 3.1 Let (in the notation above) X be a principal fibre bundle with “typical” stabilizer S . Then S is a normal subgroup in G , i.e., $S \setminus G$ is a topological group.

In a natural manner $S \setminus G$ acts continuously and freely on X . Moreover, $X/G \cong X/(S \setminus G)$.

This way the definition of a (not necessarily locally trivial) principal fibre bundle above is equivalent to the usual one. Here neither the total nor the base space gets changed. Only the acting group is reduced to its part being essential for the action. By the proposition above we see that the notation “structure group” is reasonable. It coincides with the standard definition for fibre bundles. Note, however, that the G in a “principal G -fibre bundle” X does not denote the structure group as usual, but the total acting group.

Proof Let $x \in X$ and $g \in G$. Obviously, the stabilizer of $x \circ g$ equals $G_{x \circ g} = g^{-1}G_xg = g^{-1}Sg$. Since X is a principal fibre bundle, we have $g^{-1}Sg = S$, i.e., S is a normal subgroup.

Obviously, the action $x \circ [g]_S := x \circ g$ is well-defined and continuous. Since from $x \circ [g]_S = x$ we get $x \circ g = x$, hence $g \in S$, the action is free. The homeomorphy of the two quotient spaces is clear as well. **qed**

Now we are left with the modification of the definition of trivializations.

Definition 3.2 Let G be a compact topological group, X be a principal G -fibre bundle and $\pi : X \longrightarrow X/G$ be the canonical projection. Moreover, let μ be some normalized measure on X .

1. An open G -invariant set $U \subseteq X$ is called **local trivialization** of the principal fibre bundle X iff there is an equivariant homeomorphism $\chi : U \longrightarrow \pi(U) \times (S \setminus G)$ with $\pi|_U = \text{pr}_1 \circ \chi$. Here, “equivariant” means $(\text{pr}_2 \circ \chi)(x \circ g) = ((\text{pr}_2 \circ \chi)(x)) \cdot [g]_S$ for all $x \in U$ and $g \in G$.
We often call χ itself local trivialization.

2. A principal fibre bundle is called **locally trivial** iff there is a covering $(U_\iota)_{\iota \in I}$ of X by local trivializations U_ι .
3. A principal fibre bundle is called **μ -almost globally trivial** iff there is a covering (U_ι) as in the preceding item where additionally $\mu(U_\iota) = 1$ for all ι .

In the following we usually say simply “almost global” instead of “ μ -almost global” provided the measure μ meant is clear.

4. A principal fibre bundle is called **globally trivial** iff X is a local trivialization.

Here again it should be clear that the definitions above are equivalent to the standard ones. However, we will use these definitions throughout the whole paper when we speak about principal fibre bundles and trivializations.

4 Principal Fibre Bundle Structure of the Strata

In order to decide which strata are principal fiber bundles we have to study the form of the stabilizers, i.e. of the base centralizers.

Definition 4.1 The set $\mathbf{B}_Z := \{\bar{g} \in \bar{\mathcal{G}} \mid g_m \in Z(\mathbf{G}) \text{ and } g_x = g_m \quad \forall x \in M\}$ is called **base center**.

- Lemma 4.1**
1. The base center is contained in every base centralizer.
 2. A base centralizer is a normal subgroup of $\bar{\mathcal{G}}$ iff it equals the base center.
 3. The base centralizer of a connection equals the base center iff the connection is generic.

Proof Let $\bar{A} \in \bar{\mathcal{A}}$ with base centralizer $\mathbf{B}(\bar{A})$.

1. We have

$$\begin{aligned} \bar{g} \in \mathbf{B}(\bar{A}) &\iff \begin{aligned} \text{a) } &g_m \in Z(\mathbf{H}_{\bar{A}}) \\ \text{b) } &h_{\bar{A}}(\gamma) = g_m^{-1} h_{\bar{A}}(\gamma) g_x \quad \forall \gamma \in \mathcal{P}_{mx}, x \in M. \end{aligned} \end{aligned}$$

Since $Z \subseteq Z(U)$ for all $U \subseteq \mathbf{G}$, we have $\mathbf{B}_Z \subseteq \mathbf{B}(\bar{A})$.

2. $\implies$ Let $\mathbf{B}(\bar{A})$ be a normal subgroup in $\bar{\mathcal{G}}$.

Let $\bar{g} \in \mathbf{B}(\bar{A})$ and $g_0 \in \mathbf{G}$. Furthermore, let $x \in M$, $x \neq m$, and $\gamma \in \mathcal{P}_{mx}$ be arbitrary. Additionally choose a $\bar{g}_0 \in \bar{\mathcal{G}}$ with $g_{0,m} = g_0$ and $g_{0,x} = h_{\bar{A}}(\gamma)$. Then by assumption $\bar{g}_0^{-1} \bar{g} \bar{g}_0 \in \mathbf{B}(\bar{A})$, in particular

$$\begin{aligned} h_{\bar{A}}(\gamma) &= g_{0,m}^{-1} g_m^{-1} g_{0,m} h_{\bar{A}}(\gamma) g_{0,x}^{-1} g_x g_{0,x} \\ &= g_0^{-1} g_m^{-1} g_0 h_{\bar{A}}(\gamma) h_{\bar{A}}(\gamma)^{-1} g_x h_{\bar{A}}(\gamma) \\ &= g_0^{-1} g_m^{-1} g_0 g_x h_{\bar{A}}(\gamma), \end{aligned}$$

hence $g_m g_0 = g_0 g_x$. Since g_0 is arbitrary, we have $g_m = g_x$ for all $x \in M$ and consequently $g_m \in Z$. Thus, $\bar{g} \in \mathbf{B}_Z$.

We get $\mathbf{B}(\bar{A}) \subseteq \mathbf{B}_Z$, hence the equality by the first part of the present proof.

$$\Longleftarrow \text{ Let } \mathbf{B}(\bar{A}) = \mathbf{B}_Z.$$

Let now $\bar{g} \in \mathbf{B}_Z$ and $\bar{g}_0 \in \bar{\mathcal{G}}$. Then we have $(\bar{g}_0^{-1} \bar{g} \bar{g}_0)_x = g_{0,x}^{-1} g_x g_{0,x} = g_{0,x}^{-1} g_m g_{0,x} = g_{0,x}^{-1} g_{0,x} g_m = g_m \in Z$, hence, in particular, $(\bar{g}_0^{-1} \bar{g} \bar{g}_0)_x = (\bar{g}_0^{-1} \bar{g} \bar{g}_0)_m$ for all $x \in M$. Thus, $\bar{g}_0^{-1} \bar{g} \bar{g}_0 \in \mathbf{B}_Z$. Hence, $\mathbf{B}(\bar{A}) = \mathbf{B}_Z$ is a normal subgroup.

3. $\implies$ Let $\bar{A} \notin \bar{\mathcal{A}}_{\text{gen}}$, i.e. $Z(\mathbf{H}_{\bar{A}}) \supset Z$.

Let $g \in Z(\mathbf{H}_{\bar{A}}) \setminus Z$, and set $\bar{g} := (h_{\bar{A}}(\gamma_x)^{-1} g h_{\bar{A}}(\gamma_x))_{x \in M}$ with γ_x chosen as usual. Per definitionem we have $\bar{g} \in \mathbf{B}(\bar{A})$, but $\bar{g} \notin \mathbf{B}_Z$.

$\Leftarrow$ Let $\bar{A} \in \bar{\mathcal{A}}_{\text{gen}}$, i.e. $Z(\mathbf{H}_{\bar{A}}) = Z$. Now we have

$$\begin{aligned} \bar{g} \in \mathbf{B}(\bar{A}) &\iff \begin{array}{ll} \text{a)} & g_m \in Z(\mathbf{H}_{\bar{A}}) = Z \\ \text{b)} & h_{\bar{A}}(\gamma) = g_m^{-1} h_{\bar{A}}(\gamma) g_x \quad \forall \gamma \in \mathcal{P}_{mx}, x \in M \end{array} \\ &\iff \begin{array}{ll} \text{a)} & g_m \in Z \\ \text{b)} & h_{\bar{A}}(\gamma) = h_{\bar{A}}(\gamma) g_m^{-1} g_x \quad \forall \gamma \in \mathcal{P}_{mx}, x \in M \end{array} \\ &\iff \begin{array}{ll} \text{a)} & g_m \in Z \\ \text{b)} & g_m = g_x \quad \forall x \in M \end{array} \\ &\iff \bar{g} \in \mathbf{B}_Z. \end{aligned}$$

qed

Consequently, only the generic stratum is a principal fibre bundle:

Proposition 4.2 Let $t \in \mathcal{T}$ be a gauge orbit type. Then we have:

The stratum $\bar{\mathcal{A}}_{=t}$ is a principal fibre bundle iff $t = t_{\max}$, i.e. $\bar{\mathcal{A}}_{=t} = \bar{\mathcal{A}}_{\text{gen}}$.

Proof By the definition of the gauge orbit type, all holonomy centralizers $Z(\mathbf{H}_{\bar{A}})$ occurring in a fixed stratum $\bar{\mathcal{A}}_{=t}$ are conjugate. As proven in [13] the same is true for the stabilizers $\mathbf{B}(\bar{A})$.

Now $\bar{\mathcal{A}}_{=t}$ is a principal fibre bundle iff all connections in $\bar{\mathcal{A}}_{=t}$ have the same stabilizer. On the other hand, this is true iff this stabilizer is a normal subgroup in $\bar{\mathcal{G}}$.¹ The lemma above yields the assertion. qed

5 Almost Global Triviality of $(\mathbf{G}^k)_{\text{gen}}$

In Section 7 we will prove that $\bar{\mathcal{A}}_{\text{gen}}$ is not only a locally trivial, but even an almost globally trivial principal fibre bundle. As mentioned in the introduction we will deduce this by means of the reduction mapping from the corresponding statement on the generic stratum of $\mathbf{G}^k$ w.r.t. the adjoint action that we are going to deal with in the present section.

Definition 5.1 Let $k \in \mathbb{N}_+$.

An element $\vec{g} := (g_1, \dots, g_k) \in \mathbf{G}^k$ (and its orbit, resp.) is called **generic** iff $\text{Typ}(\vec{g}) \equiv [Z(\{g_1, \dots, g_k\})] = [Z]$.

The set of all generic elements of $\mathbf{G}^k$ is denoted by $(\mathbf{G}^k)_{\text{gen}}$.

Since $\text{Typ}(\vec{g}) \leq [Z]$ for all $\vec{g} \in \mathbf{G}^k$, every generic orbit is of maximal type. Moreover, a Lie group is abelian iff one (and then each) (nontrivial) power consists of generic elements only.²

¹Let G be a group acting on X where all stabilizers G_x , $x \in X$, are conjugate. If X is a principal fibre bundle, then $G_x = G_y$ for all $x, y \in X$ and, in particular, $G_x = G_{x \circ g} = g^{-1} G_x g$ for all g . Thus, G_x is a normal subgroup in G . Conversely, let all G_x be normal subgroups. Then, since all stabilizers are conjugate, we have $G_y = g^{-1} G_x g \subseteq G_x$ for all $x, y \in X$, i.e., X is a principal fibre bundle.

²We have $Z(\vec{e}_{\mathbf{G}}) := Z((e_{\mathbf{G}}, \dots, e_{\mathbf{G}})) = \mathbf{G}$. If $\mathbf{G}^k$ now consists for $k \in \mathbb{N}_+$ of generic elements only, then $Z = Z(\vec{e}_{\mathbf{G}}) = \mathbf{G}$. Conversely, if $Z = \mathbf{G}$, then $\mathbf{G} \supseteq Z(\vec{g}) \supseteq Z = \mathbf{G}$, hence $Z(\vec{g}) = Z$ for all $\vec{g} \in \mathbf{G}^k$.

Proposition 5.1 There is a $k_{\min} \in \mathbb{N}_+$, such that the generic stratum $(\mathbf{G}^k)_{\text{gen}}$ is an open and dense submanifold of $\mathbf{G}^k$ with full Haar measure for all $k \geq k_{\min}$ and is empty for all $k < k_{\min}$.

Proof 1. Choice of $k_{\min}$

By the finiteness lemma for centralizers [13] there is a $k \in \mathbb{N}_+$, such that there is at least one orbit in $\mathbf{G}^k$ having type $[Z(\mathbf{G})]$. Now, choose for $k_{\min}$ simply the minimum of all such k .

- Obviously $(\mathbf{G}^k)_{\text{gen}} = \emptyset$ for $k < k_{\min}$.
- For $k \geq k_{\min}$ there is at least one generic element in $\mathbf{G}^k$.

Namely, let $\vec{g} := (g_1, \dots, g_{k_{\min}}) \in \mathbf{G}^{k_{\min}}$ be a generic element. Then $\vec{g}_k := (g_1, \dots, g_{k_{\min}}, e_{\mathbf{G}}, \dots, e_{\mathbf{G}}) \in \mathbf{G}^k$ is generic as well because of

$$\begin{aligned} [Z] &\geq \text{Typ}(\vec{g}_k) = [Z(\{g_1, \dots, g_{k_{\min}}, e_{\mathbf{G}}, \dots, e_{\mathbf{G}}\})] \\ &= [Z(\{g_1, \dots, g_{k_{\min}}\})] = \text{Typ}(\vec{g}) = [Z]. \end{aligned}$$

Let now $k \geq k_{\min}$ in the following.

2. $(\mathbf{G}^k)_{\text{gen}}$ is a smooth submanifold of $\mathbf{G}^k$, since the adjoint action is smooth. [6]
3. $(\mathbf{G}^k)_{\text{gen}}$ is open, since any of its points possesses an open neighbourhood whose points have at least, hence by the maximality of $[Z]$ even exactly type $[Z]$. [6]
4. Since $\mathbf{G}$ is connected, $\mathbf{G}^k/\text{Ad}$ is connected again. Again by the maximality of $[Z]$, we have $\overline{(\mathbf{G}^k)_{\text{gen}}} \equiv \overline{(\mathbf{G}^k)_Z} = \bigcup_{[\mathbf{K}] \leq [Z]} (\mathbf{G}^k)_{\mathbf{K}} = \mathbf{G}^k$. [26] Here we set $(\mathbf{G}^k)_{\mathbf{K}} = \{\vec{g} \in \mathbf{G}^k \mid \text{Typ}(\vec{g}) = [\mathbf{K}]\}$.
5. Now, $(\mathbf{G}^k)_{\mathbf{H}}$ is a smooth submanifold of $\mathbf{G}^k$ for every closed subgroup $\mathbf{H}$ of $\mathbf{G}$ with $[\mathbf{H}] < [Z]$. [26] Moreover, $\dim(\mathbf{G}^k)_{\mathbf{H}} < \dim(\mathbf{G}^k)_Z \equiv \dim(\mathbf{G}^k)_{\text{gen}} = \dim \mathbf{G}^k$. Since the Haar measure of a lower-dimensional submanifold vanishes [9, 10], we have $\mu_{\text{Haar}}((\mathbf{G}^k)_{\mathbf{H}}) = 0$. Since there are only finitely many orbit types on $\mathbf{G}^k$ [26], we get $\mu_{\text{Haar}}(\mathbf{G}^k \setminus (\mathbf{G}^k)_{\text{gen}}) = \mu_{\text{Haar}}(\bigcup_{[\mathbf{H}] < [Z]} (\mathbf{G}^k)_{\mathbf{H}}) = 0$. **qed**

Proposition 5.2 $(\mathbf{G}^k)_{\text{gen}}$ is a μ_{Haar} -almost globally trivial (smooth) principal fibre bundle having structure group $Z \backslash \mathbf{G}$ for all $k \geq k_{\min}$.

Proof 1. Bundle structure over $(\mathbf{G}^k)_{\text{gen}}/\text{Ad}$

The adjoint action of $\mathbf{G}$ on $\mathbf{G}^k$ is smooth. Hence the generic stratum $(\mathbf{G}^k)_{\text{gen}} \equiv (\mathbf{G}^k)_Z$ is a smooth submanifold and $\pi_k : (\mathbf{G}^k)_{\text{gen}} \rightarrow (\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ is a smooth (locally trivial) fibre bundle with typical fibre and structure group $Z \backslash \mathbf{G}$ ([6] and note $N(Z) = \mathbf{G}$). Since the stabilizer of any point in $(\mathbf{G}^k)_{\text{gen}}$ equals Z , π_k is (in our notation) even a principal fibre bundle over the generic stratum.

2. Choice of a neighbourhood $V_{k, \vec{v}}$ for every fixed $\vec{v} \in (\mathbf{G}^k)_{\text{gen}}$

First we cut out from the n -dimensional smooth manifold $(\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ a neighbourhood B^n of $[\vec{v}]$ diffeomorphic to an n -dimensional ball and get a remaining smooth manifold N . By general arguments [24, 29, 28] there are a simplicial complex K consisting of countably many simplices and a smooth triangulation $f : K \rightarrow N$. Let K_n denote the set of all n -cells³ of K . It can be constructed from K by deleting the $(n-1)$ -skeleton $K_{\leq n-1}$, i.e. all cells whose dimension is smaller than that of K . Now define $V_{k, \vec{v}} := \pi_k^{-1}(f(K_n) \cup \text{int } B^n)$.

³Note that here (in contrast to the standard definition) a cell $\hat{\sigma}$ is the *interior* of a simplex σ . Only for dimension 0 the cell shall be a simplex.

3. Properties of $V_{k,\vec{v}}$

- $V_{k,\vec{v}}$ is Ad-invariant.
- $\vec{v} \in V_{k,\vec{v}}$.
- Since f is a smooth triangulation, $f(K_n)$ is a smooth manifold [9] that equals the disjoint union of all $f(\hat{\sigma})$ where σ is an n -simplex of K . Since f is a homeomorphism and $\hat{\sigma}$ always contractible, also $f(\hat{\sigma})$ is always contractible. The contractibility of $\text{int } B^n$ is trivial. Moreover, $\text{int } B^n$ and $f(K_n)$ are disjoint.
- Hence, as a π_k -preimage of a submanifold of $(\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ the set $V_{k,\vec{v}}$ is a submanifold of $(\mathbf{G}^k)_{\text{gen}}$, thus of $\mathbf{G}^k$ as well. In particular, $V_{k,\vec{v}}$ is open in $\mathbf{G}^k$ by the continuity of π_k . Thus $\pi_k(V_{k,\vec{v}})$ is a disjoint union of contractible manifolds.
- We have $V_{k,\vec{v}} = (\mathbf{G}^k)_{\text{gen}} \setminus \left(\pi_k^{-1}(\partial B^n) \cup \bigcup_{\sigma \in K_{\leq n-1}} \pi_k^{-1}(f(\hat{\sigma})) \right)$, i.e. $V_{k,\vec{v}}$ emerges from $(\mathbf{G}^k)_{\text{gen}}$ by deleting the π_k -preimages of the boundary of B^n and of all images of lower-dimensional skeletons in $(\mathbf{G}^k)_{\text{gen}}/\text{Ad}$, respectively.
- We have $\mu_{\text{Haar}}(V_{k,\vec{v}}) = 1$.
Since $\mu_{\text{Haar}}((\mathbf{G}^k)_{\text{gen}}) = 1$, it is sufficient to prove that the just eliminated objects have Haar measure 0.

a) Let $\sigma \in K_{\leq n-1}$. Since f is a homeomorphism, we have $\dim f(\hat{\sigma}) = \dim \hat{\sigma} < n$. As above $\pi_k^{-1}(f(\hat{\sigma}))$ is a submanifold of $(\mathbf{G}^k)_{\text{gen}}$, hence also of $\mathbf{G}^k$, whose codimension is $n - \dim \hat{\sigma} > 0$. Thus, this set is a zero set, too.

Together with K , obviously also $K_{\leq n-1}$ is a complex with countably many simplices. Hence,

$$\mu_{\text{Haar}}\left(\bigcup_{\sigma \in K_{\leq n-1}} \pi_k^{-1}(f(\hat{\sigma}))\right) \leq \sum_{\sigma \in K_{\leq n-1}} \mu_{\text{Haar}}(\pi_k^{-1}(f(\hat{\sigma}))) = 0.$$

b) ∂B^n is a smooth submanifold of $(\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ with codimension 1. Thus, $\pi_k^{-1}(\partial B^n)$ is a smooth submanifold of $(\mathbf{G}^k)_{\text{gen}}$ with codimension 1.

Again, $\mu_{\text{Haar}}(\pi_k^{-1}(\partial B^n)) = 0$.

- $V_{k,\vec{v}}$ is dense in $\mathbf{G}^k$. This follows from $\mu_{\text{Haar}}(V_{k,\vec{v}}) = 1$ and the strict positivity of the Haar measure because $V_{k,\vec{v}}$ is open.

4. Triviality of $\pi_k|_{V_{k,\vec{v}}}$

$\pi_k|_{V_{k,\vec{v}}} : V_{k,\vec{v}} \longrightarrow \pi_k(V_{k,\vec{v}}) = \text{int } B^n \cup f(K_n)$ is a principal fibre bundle over the disjoint union $\text{int } B^n \cup f(K_n)$ of contractible manifolds having structure group $Z \setminus \mathbf{G}$. Hence [18], this bundle is trivial, i.e., there is an equivariant homeomorphism $V_{k,\vec{v}} \cong \pi(V_{k,\vec{v}}) \times (Z \setminus \mathbf{G})$.

5. Almost global triviality of $(\mathbf{G}^k)_{\text{gen}}$

Obviously $\mathcal{V}_k := \{V_{k,\vec{v}} \mid \vec{v} \in (\mathbf{G}^k)_{\text{gen}}\}$ is a non-empty covering of $(\mathbf{G}^k)_{\text{gen}}$ by μ_{Haar} -almost global trivializations. qed

6 Relations between the Structure Groups

We know already that the structure group of the principal fibre bundle $(\mathbf{G}^k)_{\text{gen}}$ equals $Z \setminus \mathbf{G}$ and that of the principal fibre bundle $\overline{\mathcal{A}}_{\text{gen}}$ equals $\mathbf{B}_Z \setminus \overline{\mathcal{G}}$. In order to lift the almost global triviality of $(\mathbf{G}^k)_{\text{gen}}$ to that of $\overline{\mathcal{A}}_{\text{gen}}$ in the next section, we have to investigate the relation between the corresponding structure groups. We need

Definition 6.1 Let $* : (Z \setminus \mathbf{G}) \times \overline{\mathcal{G}} \longrightarrow \mathbf{B}_Z \setminus \overline{\mathcal{G}}$ be defined by $[g]_Z * \overline{g} := [(g g_x)_{x \in M}]_{\mathbf{B}_Z}$.

Lemma 6.1 • $*$ is well-defined and continuous.
 • The restriction of $*$ to $(Z \setminus \mathbf{G}) \times \overline{\mathcal{G}}_0$ is an isomorphism.

We recall $\overline{\mathcal{G}}_0 := \{\overline{g} \in \overline{\mathcal{G}} \mid g_m = e_{\mathbf{G}}\}$.

Proof • Let $g_1 \sim g_2$, i.e. $g_1 = z g_2$ for a $z \in Z$. Then we have

$$\begin{aligned} [g_1]_Z * \overline{g} &= [(g_1 g_x)_{x \in M}]_{\mathbf{B}_Z} \\ &= [(z g_2 g_x)_{x \in M}]_{\mathbf{B}_Z} \\ &= [\overline{z} \circ (g_2 g_x)_{x \in M}]_{\mathbf{B}_Z} \quad (\overline{z} \equiv (z)_{x \in M} \in \mathbf{B}_Z) \\ &= [(g_2 g_x)_{x \in M}]_{\mathbf{B}_Z} \\ &= [g_2]_Z * \overline{g}. \end{aligned}$$

- The continuity of $*$ follows immediately from the surjectivity and openness of the canonical projection $\mathbf{G} \times \overline{\mathcal{G}} \longrightarrow (Z \setminus \mathbf{G}) \times \overline{\mathcal{G}}$, the continuity of $\mathbf{G} \times \overline{\mathcal{G}} \longrightarrow \overline{\mathcal{G}}$ with $(g, \overline{g}) \longmapsto (g g_x)_{x \in M}$ as well as that of the canonical projection $\overline{\mathcal{G}} \longrightarrow \mathbf{B}_Z \setminus \overline{\mathcal{G}}$ and the commutativity of the corresponding diagram

$$\begin{array}{ccc} \mathbf{G} \times \overline{\mathcal{G}} & \longrightarrow & \overline{\mathcal{G}} \\ \downarrow & & \downarrow \\ (Z \setminus \mathbf{G}) \times \overline{\mathcal{G}} & \xrightarrow{*} & \mathbf{B}_Z \setminus \overline{\mathcal{G}} \end{array}.$$

- $*$ is injective.
 Let $[g_1]_Z * \overline{g}_1 = [g_2]_Z * \overline{g}_2$ with $\overline{g}_1, \overline{g}_2 \in \overline{\mathcal{G}}_0$, i.e. $g_{1,m} = g_{2,m} = e_{\mathbf{G}}$. Then per def. $[(g_1 g_{1,x})_{x \in M}]_{\mathbf{B}_Z} = [(g_2 g_{2,x})_{x \in M}]_{\mathbf{B}_Z}$. Thus, there is a $z \in Z$ with $g_1 g_{1,x} = z g_2 g_{2,x}$ for all $x \in M$. For $x = m$ we have $g_1 = z g_2$ (and so $[g_1]_Z = [g_2]_Z$) and consequently $\overline{g}_1 = \overline{g}_2$.
- $*$ is surjective.
 Let $[\overline{g}]_{\mathbf{B}_Z}$ be given. Choose a representative $\overline{g}' \in [\overline{g}]_{\mathbf{B}_Z}$. Set $g'' := g'_m$ and $g''_x := (g'')^{-1} g'_x$. Then $[g'']_Z * \overline{g}'' = [\overline{g}]_{\mathbf{B}_Z}$. **qed**

The map $*$ is a modification of the isomorphism $\Psi_0 : \overline{\mathcal{G}}_0 \times Z(\mathbf{H}_{\overline{A}}) \setminus \mathbf{G} \longrightarrow \mathbf{B}(\overline{A}) \setminus \overline{\mathcal{G}}$ [13], tailored to the special case of generic connections. There we started with the canonical isomorphism $\phi'|_{Z(\mathbf{H}_{\overline{A}})} = \phi^{-1} : Z(\mathbf{H}_{\overline{A}}) \longrightarrow \mathbf{B}(\overline{A})$, $g \longmapsto (h_{\overline{A}}(\gamma_x)^{-1} g h_{\overline{A}}(\gamma_x))_{x \in M}$ and extended it in a natural way to the whole $\mathbf{G}$. For generic connections, $\phi'|_Z$ now maps g simply on $(h_{\overline{A}}(\gamma_x)^{-1} g h_{\overline{A}}(\gamma_x))_{x \in M} = (g)_{x \in M}$. But, therewith we get a second natural extension of $\phi'|_Z$ to the whole $\mathbf{G}$. This is just the definition of $*$ above.

7 Almost Global Triviality of $\overline{\mathcal{A}}_{\text{gen}}$

We start with

Proposition 7.1 $\overline{\mathcal{A}}_{\text{gen}}$ has the induced Haar measure 1.

Proof By Proposition 5.1, $(\mathbf{G}^k)_{\text{gen}}$ has Haar measure 1 for some $k \in \mathbb{N}_+$. Now, let Γ be some graph with k edges α_i and the vertex m . Since the corresponding reduction

mapping $\varphi \equiv \pi_\Gamma : \overline{\mathcal{A}} \longrightarrow \mathbf{G}^k$ decreases the type, [13] we have $[Z] = \text{Typ}(\varphi(\overline{A})) \leq \text{Typ}(\overline{A}) \leq [Z]$ for all $\overline{A} \in \varphi^{-1}((\mathbf{G}^k)_{\text{gen}})$. Hence $\overline{\mathcal{A}}_{\text{gen}} \supseteq \varphi^{-1}((\mathbf{G}^k)_{\text{gen}})$. By definition of the induced Haar measure,

$$1 \geq \mu_0(\overline{\mathcal{A}}_{\text{gen}}) \geq \mu_0(\varphi^{-1}((\mathbf{G}^k)_{\text{gen}})) = \mu_{\text{Haar}}((\mathbf{G}^k)_{\text{gen}}) = 1. \quad \text{qed}$$

The goal of the present section is the proof of the following

Theorem 7.2 $\overline{\mathcal{A}}_{\text{gen}}$ is (w.r.t. the action of $\overline{\mathcal{G}}$) a μ_0 -almost globally trivial principal fibre bundle with structure group $\mathbf{B}_Z \setminus \overline{\mathcal{G}}$.

7.1 Independent Generators of the Holonomy Centralizer

Our task is to find for all $\overline{A} \in \overline{\mathcal{A}}_{\text{gen}}$ a neighbourhood $U_{\overline{A}}$ that, on the one hand, has the full measure 1 and, on the other hand, is a local trivialization of $\overline{\mathcal{A}}_{\text{gen}}$. For that purpose we choose for $\overline{A}$ according to the finiteness lemma for centralizers [13] finitely many paths α_i in $\mathcal{HG}$ with $Z(h_{\overline{A}}(\alpha)) = Z(\mathbf{H}_{\overline{A}}) = Z$ and denote the corresponding reduction mapping shortly by φ . The most obvious choice of a neighbourhood of $\overline{A}$ would be $U := \varphi^{-1}(V)$, where V is an almost global trivialization of $(\mathbf{G}^k)_{\text{gen}}$ from the covering above with $\varphi(\overline{A}) \in V$. But, it can happen that despite of $\mu_{\text{Haar}}(V) = 1$ the induced Haar measure of U is *smaller than* 1. This is, in particular, the case if φ is not surjective, because, e.g., the paths in α are not independent or one path in α occurs twice what is not a priori forbidden. That is why we have to guarantee that we can always find an α fulfilling a certain independency condition. For that purpose we will need the notion of hyphs [12]: A hyph v is a set of “independent” paths. For instance, graphs and webs [4] are special hyphs. One of the most striking properties of a hyph is that the parallel transports can be assigned to the paths independently. Moreover, the corresponding projection $\pi_v : \overline{\mathcal{A}} \longrightarrow \mathbf{G}^{\#v}$, $\overline{A} \longmapsto h_{\overline{A}}(v)$, gives $\mu_0(\pi_v^{-1}(W)) = \mu_{\text{Haar}}(W)$ for all W .

It would be optimal if we were able to show that for every $\overline{A}$ there is a hyph α with $Z(\mathbf{H}_{\overline{A}}) = Z(h_{\overline{A}}(\alpha))$. However, though we can find – starting with an arbitrary β with $Z(\mathbf{H}_{\overline{A}}) = Z(h_{\overline{A}}(\beta))$ – a hyph v such that all paths in β can be written as products of paths in v , this set v typically consists not only of paths in $\mathcal{HG}$, i.e. closed paths only. To avoid this problem we weaken the notion of a hyph.

Definition 7.1 A finite set $\alpha \subseteq \mathcal{HG}$ is called **weak hyph** iff the corresponding reduction mapping

$$\begin{aligned} \varphi_\alpha : \overline{\mathcal{A}} &\longrightarrow \mathbf{G}^{\#\alpha} \\ \overline{A}' &\longmapsto h_{\overline{A}'}(\alpha) \end{aligned}$$

is surjective and fulfills

$$\mu_0(\pi_\alpha^{-1}(W)) = \mu_{\text{Haar}}(W) \text{ for all } W \subseteq \mathbf{G}^{\#\alpha}.$$

Obviously, every hyph that consists only of closed paths is a weak hyph.

Proposition 7.3 For every $\overline{A} \in \overline{\mathcal{A}}$ there is a weak hyph $\alpha \subseteq \mathcal{HG}$ with $Z(h_{\overline{A}}(\alpha)) = Z(\mathbf{H}_{\overline{A}})$.

The proof of this proposition is very technical and is therefore shifted to Appendix F.

7.2 Choice of the Covering of $\overline{\mathcal{A}}_{\text{gen}}$

Now, we are able to define the desired covering of $\overline{\mathcal{A}}_{\text{gen}}$: For each $\overline{A} \in \overline{\mathcal{A}}_{\text{gen}}$ we choose a weak hyph $\alpha \subseteq \mathcal{HG}$ with $Z(h_{\overline{A}}(\alpha)) = Z(\mathbf{H}_{\overline{A}}) = Z$ by Proposition 7.3 and denote the corresponding reduction mapping as usual by φ_{α} . Now we choose according to Section 5 an almost global trivialization $V_{\# \alpha, \varphi_{\alpha}(\overline{A})}$ of $(\mathbf{G}^{\# \alpha})_{\text{gen}}$ that contains $\varphi_{\alpha}(\overline{A})$, and set $U_{\overline{A}} := \varphi_{\alpha}^{-1}(V_{\# \alpha, \varphi_{\alpha}(\overline{A})}) \subseteq \overline{\mathcal{A}}$. By $\overline{A} \in U_{\overline{A}}$ we have

Proposition 7.4 $\mathcal{U} := \{U_{\overline{A}}\}_{\overline{A} \in \overline{\mathcal{A}}_{\text{gen}}}$ is a covering of $\overline{\mathcal{A}}_{\text{gen}}$.

7.3 Properties of the Covering

We still have to show that each $U_{\overline{A}}$ is an almost global trivialization of $\overline{\mathcal{A}}_{\text{gen}}$. For this, let us fix an arbitrary $\overline{A} \in \overline{\mathcal{A}}_{\text{gen}}$ with reduction mapping $\varphi := \varphi_{\alpha}$ and set simply $k := \# \alpha$, $V := V_{k, \varphi(\overline{A})} \subseteq (\mathbf{G}^k)_{\text{gen}}$ and $U := U_{\overline{A}} = \varphi^{-1}(V)$.

The easily verifiable properties of U are described by

Lemma 7.5 U is an open, dense, $\overline{\mathcal{G}}$ -invariant subset of $\overline{\mathcal{A}}_{\text{gen}}$ with $\mu_0(U) = 1$.

Proof By construction, V is an open, dense, Ad-invariant subset of $(\mathbf{G}^k)_{\text{gen}}$ with $\mu_{\text{Haar}}(V) = 1$. Since φ always preserves or reduces the types, [13] we have $[Z] = \text{Typ}(\varphi(\overline{A}')) \leq \text{Typ}(\overline{A}') \leq [Z]$, i.e. $\overline{A}' \in \overline{\mathcal{A}}_{\text{gen}}$ for all $\overline{A}' \in U$. Since φ is continuous, $U = \varphi^{-1}(V)$ is open as a subset of $\overline{\mathcal{A}}$, hence as a subset of $\overline{\mathcal{A}}_{\text{gen}}$ as well due to the openness of $\overline{\mathcal{A}}_{\text{gen}}$. Since α is a weak hyph, we have $\mu_0(U) = \mu_0(\varphi^{-1}(V)) = \mu_{\text{Haar}}(V) = 1$ by Proposition 7.3. Due to the strict positivity of μ_0 , both statements yield the denseness of U in $\overline{\mathcal{A}}_{\text{gen}}$. Finally, the $\overline{\mathcal{G}}$ -invariance of U follows from the Ad-invariance of V . **qed**

The most important property of U , however, requires a longer proof.

Proposition 7.6 U is a local trivialization of $\overline{\mathcal{A}}_{\text{gen}}$.

Proof We denote the equivariant homeomorphism that belongs to the almost global trivialization of $\mathbf{G}^k$ according Proposition 5.2 by $\psi : V \longrightarrow \pi_k(V) \times (Z \setminus \mathbf{G})$. The projection onto the second component be $\psi_2 : V \longrightarrow Z \setminus \mathbf{G}$. Furthermore, let γ_x be for every $x \in M$ some fixed path from m to x . W.l.o.g., γ_m is the trivial path.

Now we define the trivialization mapping of $\overline{\mathcal{A}}$:

$$\begin{aligned} \Psi : U &\longrightarrow \pi(U) \times \mathbf{B}_Z \setminus \overline{\mathcal{G}}. \\ h &\longmapsto ([h], \psi_2(\varphi(h)) * (h(\gamma_x))_{x \in M}) \end{aligned}$$

1. Ψ is well-defined.

Because of $h \in U$ we have $\varphi(h) \in V$, i.e. $\psi_2(\varphi(h))$ is well-defined.

2. Ψ is surjective.

Let $([h], [\overline{g}]_{\mathbf{B}_Z}) \in \pi(U) \times \mathbf{B}_Z \setminus \overline{\mathcal{G}}$ be given. By Lemma 6.1 there is exactly one $[g']_Z \in Z \setminus \mathbf{G}$ and some $\overline{g}' \in \overline{\mathcal{G}}_0$ with $[g']_Z * \overline{g}' = [\overline{g}]_{\mathbf{B}_Z}$. Additionally choose some $h' \in [h]$. Hence, $h' \in U$ and $\varphi(h') \equiv h'(\alpha) \in V$. Let $\vec{g} := \psi^{-1}([h'(\alpha)]_{\text{Ad}}, [g']_Z)$. Since $h'(\alpha)$ and $\vec{g}$ are in one and the same orbit w.r.t. the adjoint action, there is a $\tilde{g} \in \mathbf{G}$ with $\vec{g} = \tilde{g}^{-1} h'(\alpha) \tilde{g}$. Now, let $\tilde{h}(\gamma) := (g'_x)^{-1} \tilde{g}^{-1} h'(\gamma_x \gamma \gamma_y^{-1}) \tilde{g} g'_y$ for all $\gamma \in \mathcal{P}_{xy}$.

Obviously, $\bar{h}$ is gauge equivalent to h' by means of the gauge transform $(h'(\gamma_x)^{-1}\tilde{g}g'_x)_{x \in M}$. Hence $[\bar{h}] = [h'] = [h]$ and $\bar{h} \in U$. Moreover, $\varphi(\bar{h}) \equiv \bar{h}(\alpha) = \tilde{g}^{-1}h'(\alpha)\tilde{g}$. Finally,

$$\begin{aligned}\Psi(\bar{h}) &= ([\bar{h}], \psi_2(\varphi(\bar{h})) * (\bar{h}(\gamma_x))_{x \in M}) \\ &= ([h], \psi_2(\tilde{g}^{-1}h'(\alpha)\tilde{g}) * ((g'_m)^{-1}\tilde{g}^{-1}h'(1)\tilde{g}g'_x)_{x \in M}) \\ &= ([h], \psi_2(\tilde{g}) * (g'_x)_{x \in M}) \\ &= ([h], [g']_Z * \bar{g}) \\ &= ([h], [\bar{g}]_{\mathbf{B}_Z}).\end{aligned}$$

3. Ψ is injective.

Let $\Psi(h_1) = \Psi(h_2)$. Then, in particular, $\psi_2(\varphi(h_1)) * (h_1(\gamma_x))_{x \in M} = \psi_2(\varphi(h_2)) * (h_2(\gamma_x))_{x \in M}$. From the bijectivity of $*$ on $(Z \setminus \mathbf{G}) \times \bar{\mathcal{G}}_0$ we get $h_1(\gamma_x) = h_2(\gamma_x)$ for all $x \in M$ and $\psi_2(h_1(\alpha)) = \psi_2(h_2(\alpha))$. Since by assumption h_1 and h_2 are gauge equivalent, there is a $\bar{g} \in \bar{\mathcal{G}}$ with $h_1 = h_2 \circ \bar{g}$. In particular, we have $h_1(\alpha) = g_m^{-1}h_2(\alpha)g_m$, i.e., $h_1(\alpha)$ and $h_2(\alpha)$ are contained in the same orbit. Due to $\psi_2(h_1(\alpha)) = \psi_2(h_2(\alpha))$ we have $h_2(\alpha) = h_1(\alpha) = g_m^{-1}h_2(\alpha)g_m$, i.e. $g_m \in Z(h_2(\alpha)) = Z$. Finally we get $g_x = h_2(\gamma_x)^{-1}g_m h_1(\gamma_x) = h_2(\gamma_x)^{-1}h_1(\gamma_x)g_m = g_m$ for all $x \in M$, i.e. $\bar{g} \in \mathbf{B}_Z$. Due to $h_1, h_2 \in U$, we get $h_1 = h_2 \circ \bar{g} = h_2$.

4. Ψ is continuous.

It is sufficient to prove that the projections from Ψ onto the two factors are continuous:

- $\Psi_1 := \text{pr}_1 \circ \Psi$ is equal to $\pi : U \longrightarrow \pi(U)$, hence continuous.
- $\Psi_2 := \text{pr}_2 \circ \Psi$ is continuous as a concatenation of continuous mappings $\varphi, \psi_2, \pi_{\gamma_x}$ and $*$.⁴

5. Ψ is a homeomorphism.⁵

Since f is bijective and continuous, we only have to show (cf. Proposition G.1 in Appendix G), that every element of $\pi(U) \times \mathbf{B}_Z \setminus \bar{\mathcal{G}}$ has a compact neighbourhood whose preimage is again compact in U . Let now such an element $([h'], [\bar{g}]_{\mathbf{B}_Z})$ be given. Since U is an open subset of the compact Hausdorff space $\bar{\mathcal{A}}$, U is locally compact. Hence, there is a compact neighbourhood $U' \subseteq U$ of h' . Now, $W := \pi(U') \times \mathbf{B}_Z \setminus \bar{\mathcal{G}}$ is the desired compact neighbourhood of $([h'], [\bar{g}]_{\mathbf{B}_Z})$: Due to the compactness of U' and $\bar{\mathcal{G}}$, W is compact and by the openness of π also a neighbourhood; moreover, $\pi^{-1}(W) = U' \circ \bar{\mathcal{G}}$ is (again by the compactness of $\bar{\mathcal{G}}$) compact.

6. Ψ is equivariant.

We have

$$\begin{aligned}\Psi(h \circ \bar{g}) &= ([h \circ \bar{g}], \psi_2(\varphi(h \circ \bar{g})) * ((h \circ \bar{g})(\gamma_x))_{x \in M}) \\ &= ([h], \psi_2(\varphi(h) \circ g_m) * ((g_m^{-1}h(\gamma_x)g_x)_{x \in M})) \\ &= ([h], (\psi_2(\varphi(h)) \cdot [g_m]_Z) * ((g_m^{-1}h(\gamma_x)g_x)_{x \in M})) \\ &\quad (\cdot \text{ denotes the multiplication in } Z \setminus \mathbf{G}.) \\ &= ([h], \psi_2(\varphi(h)) * (h(\gamma_x)g_x)_{x \in M})\end{aligned}$$

⁴ $\pi_{\gamma_x} : \bar{\mathcal{A}} \longrightarrow \mathbf{G}, \bar{A} \longmapsto h_{\bar{A}}(\gamma_x)$.

⁵Note that the standard theorem on the continuity of the inverse mapping is not applicable because U is typically noncompact.

$$\begin{aligned}
&= ([h], (\psi_2(\varphi(h)) * (h(\gamma_x))_{x \in M}) \cdot [\bar{g}]_{\mathbf{B}_Z}) \\
&\quad (\cdot \text{ now denotes multiplication in } \mathbf{B}_Z \setminus \bar{\mathcal{G}}.) \\
&= \Psi(h) \circ [\bar{g}]_{\mathbf{B}_Z}.
\end{aligned}$$

qed

7.4 Proof of Theorem 7.2

Proof Theorem 7.2

By Proposition 2.1, $\bar{\mathcal{A}}_{\text{gen}}$ is (w.r.t. the action of $\bar{\mathcal{G}}$) a fibre bundle with structure group $Z \setminus \mathbf{G}$ and by Proposition 4.2 even a principal fibre bundle. The lemmata and propositions of the present section show that $\mathcal{U}$ is a covering of $\bar{\mathcal{A}}_{\text{gen}}$ by almost global trivializations. qed

8 Triviality of $\bar{\mathcal{A}}$ for Abelian $\mathbf{G}$

For commutative structure groups every connection is generic. Moreover, $\bar{\mathcal{A}}$ is even globally trivial:

Proposition 8.1 Let $\mathbf{G}$ be a commutative compact Lie group.

Then $\bar{\mathcal{A}}$ is a globally trivial principal fibre bundle with structure group $\bar{\mathcal{G}}_{\text{const}} \setminus \bar{\mathcal{G}}$.

Here, $\bar{\mathcal{G}}_{\text{const}}$ denoted the set of all constant gauge transforms. Obviously, $\bar{\mathcal{G}}_{\text{const}}$ equals the base center. $\bar{\mathcal{G}}_{\text{const}} \setminus \bar{\mathcal{G}}$ is isomorphic to $\bar{\mathcal{G}}_0$ as a topological group via $[\bar{g}]_{\bar{\mathcal{G}}_{\text{const}}} \mapsto (g_m^{-1} g_x)_{x \in M}$. Therefore one can (after an appropriate modification of the action) regard $\bar{\mathcal{A}}$ in the abelian case as a principal $\bar{\mathcal{G}}_0$ -fibre bundle over $\bar{\mathcal{A}}/\bar{\mathcal{G}}$.

Proof Let

$$\begin{aligned}
\Psi : \bar{\mathcal{A}} &\longrightarrow \bar{\mathcal{A}}/\bar{\mathcal{G}} \times \bar{\mathcal{G}}_{\text{const}} \setminus \bar{\mathcal{G}}, \\
h &\longmapsto ([h], [(h(\gamma_x))_{x \in M}])
\end{aligned}$$

where γ_x is as usual for all $x \in M$ some path from m to x being trivial for $x = m$.

In a commutative group the adjoint action is trivial, hence

$$\bar{\mathcal{A}}/\bar{\mathcal{G}} = \text{Hom}(\mathcal{H}\mathcal{G}, \mathbf{G})/\text{Ad} = \text{Hom}(\mathcal{H}\mathcal{G}, \mathbf{G}).$$

1. Ψ is surjective.

Let $[h] \in \bar{\mathcal{A}}/\bar{\mathcal{G}}$ and $[\bar{g}] \in \bar{\mathcal{G}}_{\text{const}} \setminus \bar{\mathcal{G}}$ be given. As just remarked there is an $h' \in \bar{\mathcal{A}}$ with $h'|_{\mathcal{H}\mathcal{G}} = [h]$. Now, let $h''(\gamma) := g_x^{-1} h'(\gamma_x \gamma \gamma_y^{-1}) g_y$ for $\gamma \in \mathcal{P}_{xy}$. Obviously, $h'' \in \bar{\mathcal{A}}$ and $\Psi(h'') = ([h], [\bar{g}])$.

2. Ψ is injective.

Let $h_1, h_2 \in \bar{\mathcal{A}}$ and $\Psi(h_1) = \Psi(h_2)$. Then $[(h_1(\gamma_x))_{x \in M}] = [(h_2(\gamma_x))_{x \in M}]$, hence $-\gamma_m$ is trivial – also $h_1(\gamma_x) = h_2(\gamma_x)$ for all $x \in M$. The injectivity now follows, because two connections are equal if their holonomies are equal and if their parallel transports coincide for each x along at least one path from m to x .

3. Ψ is obviously continuous.

4. Ψ^{-1} is continuous because $\bar{\mathcal{A}}$ is compact and $\bar{\mathcal{A}}/\bar{\mathcal{G}} \times \bar{\mathcal{G}}_{\text{const}} \setminus \bar{\mathcal{G}}$ is Hausdorff.

5. Ψ is clearly equivariant. qed

9 Criterion for the Non-Triviality of $\overline{\mathcal{A}}_{\text{gen}}$

We already know that $\overline{\mathcal{A}}_{\text{gen}}$ is almost globally trivial and in the abelian case even globally trivial. Now we want to know when the generic stratum is nontrivial. First we state a sufficient condition for the non-triviality of $\overline{\mathcal{A}}_{\text{gen}}$ requiring only a property of $\mathbf{G}$ and find then a class of Lie groups having this property. Finally we discuss some problems arising when we tried to prove that $\overline{\mathcal{A}}_{\text{gen}}$ is nontrivial for *all* non-commutative $\mathbf{G}$.

9.1 General Criterion

We start with the sufficient condition for the non-triviality of $\overline{\mathcal{A}}_{\text{gen}}$.

Proposition 9.1 If there is a natural number $k \geq 1$ such that $(\mathbf{G}^k)_{\text{gen}}$ is a nontrivial principal $\mathbf{G}$ -fibre bundle, then $\overline{\mathcal{A}}_{\text{gen}}$ (and thus $\overline{\mathcal{A}}$) is nontrivial as well.

Proof Let $k \in \mathbb{N}_+$ and $(\mathbf{G}^k)_{\text{gen}}$ nontrivial.

Suppose there were a section $s : \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}} \rightarrow \overline{\mathcal{A}}_{\text{gen}}$ for $\pi : \overline{\mathcal{A}}_{\text{gen}} \rightarrow \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$. We choose a graph Γ with k edges and exactly one vertex m . The set of edges is denoted by $\alpha \subseteq \mathcal{HG}$ and defines the reduction mapping $\varphi := \varphi_\alpha$. Moreover, we define $U := \varphi^{-1}((\mathbf{G}^k)_{\text{gen}})$. Our goal is now to construct a section $s_{[\varphi]}$ in the bottom line of the diagram

$$\begin{array}{ccccc} \overline{\mathcal{A}}_{\text{gen}} & \xleftarrow{\supseteq} & U & \xleftarrow{s_\varphi} & (\mathbf{G}^k)_{\text{gen}} \\ \uparrow s & & \uparrow s|_U & & \uparrow \pi_k \\ \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}} & \xleftarrow{\supseteq} & [U] & \xleftarrow{[\varphi]} & (\mathbf{G}^k)_{\text{gen}}/\text{Ad} \\ & & \downarrow \pi|_U & & \downarrow s_k \end{array}$$

We will see that $\varphi \circ s \circ s_{[\varphi]}$ induces a continuous section for $\pi_k : (\mathbf{G}^k)_{\text{gen}} \rightarrow (\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ that, however, does not exist by assumption.

We construct first a section $s_\varphi : (\mathbf{G}^k)_{\text{gen}} \rightarrow \overline{\mathcal{A}}_{\text{gen}}$. Here we choose for $s_\varphi(\vec{g})$ that connection, that is build by means of the construction method [12] out of the trivial connection if one successively assigns the components of $\vec{g}$ to the k edges in Γ . Clearly, then $\varphi(s_\varphi(\vec{g})) = \vec{g}$ for all $\vec{g} \in \mathbf{G}^k$. It is easy to see⁶ from this method, that s_φ is continuous and obviously maps $(\mathbf{G}^k)_{\text{gen}}$ to $\overline{\mathcal{A}}_{\text{gen}}$.

Now we define for $[\vec{g}] \in (\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ a mapping $s_{[\varphi]} : (\mathbf{G}^k)_{\text{gen}}/\text{Ad} \rightarrow \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$ by $s_{[\varphi]}([\vec{g}]) := \pi(s_\varphi(\vec{g}))$.

- $s_{[\varphi]}$ is well-defined.

Let $\vec{g}_2 = \vec{g}_1 \circ g$, $g \in \mathbf{G}$. Then $s_\varphi(\vec{g}_2) = s_\varphi(\vec{g}_1) \circ \bar{g}$, where $\bar{g} \in \overline{\mathcal{G}}$ is that gauge transform having the value g everywhere. Hence $s_{[\varphi]}([\vec{g}_1]) = s_{[\varphi]}([\vec{g}_2])$.

- $s_{[\varphi]}$ is a section.

As just proven we have $s_{[\varphi]} \circ \pi_k = \pi \circ s_\varphi$, thus

⁶Let e be some edge in M . There are at most two indices i and j such that the initial paths of α_i and α_j coincide with a partial path of e or e^{-1} . If there were no such indices, then $\pi_e \circ s_\varphi(\vec{g}) = e_{\mathbf{G}}$ for all $\vec{g}$. Otherwise $\pi_e \circ s_\varphi(\vec{g})$ equals a product of g_i , g_j , g_i^{-1} or g_j^{-1} . Thus, in any case $\pi_e \circ s_\varphi : \mathbf{G}^k \rightarrow \mathbf{G}$ is continuous for all edges e . Hence, s_φ is continuous as well.

$$\begin{aligned}
[\varphi] \circ s_{[\varphi]} &= [\varphi] \circ s_{[\varphi]} \circ \pi_k \circ (\pi_k)^{-1} && \text{(Surjectivity of } \pi_k) \\
&= [\varphi] \circ \pi \circ s_\varphi \circ (\pi_k)^{-1} \\
&= \pi_k \circ \varphi \circ s_\varphi \circ (\pi_k)^{-1} && \text{(Commutativity of projections)} \\
&= \pi_k \circ (\pi_k)^{-1} && \text{(Section property)} \\
&= \text{id}_{(\mathbf{G}^k)_{\text{gen}}/\text{Ad}}. && \text{(Surjectivity of } \pi_k)
\end{aligned}$$

- $s_{[\varphi]}$ is continuous.

By the quotient criterion, $s_{[\varphi]}$ is continuous iff $s_{[\varphi]} \circ \pi_k$ is continuous. But, the latter one is equal to $\pi \circ s_\varphi$, hence continuous.

Finally we prove that $s_k := \varphi \circ s \circ s_{[\varphi]}$ is a section for π_k : We have

$$\pi_k \circ s_k = \pi_k \circ \varphi \circ s \circ s_{[\varphi]} = [\varphi] \circ \pi \circ s \circ s_{[\varphi]} = \text{id}_{(\mathbf{G}^k)_{\text{gen}}/\text{Ad}},$$

because s and $s_{[\varphi]}$ are sections themselves. The continuity of s_k is clear. Hence, there is a global continuous section in $\pi_k : (\mathbf{G}^k)_{\text{gen}} \longrightarrow (\mathbf{G}^k)_{\text{gen}}/\text{Ad}$. This is a contradiction to the assumption that π_k is a nontrivial bundle.

Therefore, there is no continuous section over the whole $\overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$. **qed**

9.2 Concrete Criterion

The crucial question is now what concrete $\mathbf{G}$ and k give nontrivial bundles $\pi_k : (\mathbf{G}^k)_{\text{gen}} \longrightarrow (\mathbf{G}^k)_{\text{gen}}/\text{Ad}$. It is quite easy to see (cf. Appendix B) that in the case of $\mathbf{G} = SU(2)$ the bundle is empty for $k = 1$, trivial for $k = 2$ and nontrivial for $k \geq 3$. So maybe typically up to some k the bundles are trivial, but nontrivial for bigger k . But, is there a k for *every* non-abelian $\mathbf{G}$ such that π_k is nontrivial?

Up to now, we did not find a complete answer. However, the following two propositions give a wide class of groups, for which the bundle is nontrivial starting at some k . In particular, the proposition above is non-empty, i.e., its assumptions can be fulfilled.

Proposition 9.2 Let $\mathbf{G}$ be a non-abelian Lie group with $\pi_1^h(Z \setminus \mathbf{G}) \neq 1$ and $\pi_1^h(\mathbf{G}) = 1$.⁷
Then there is a $k \in \mathbb{N}$ such that $(\mathbf{G}^k)_{\text{gen}}$ is a nontrivial principal $\mathbf{G}$ -fibre bundle.

Proof • Choose $k' \in \mathbb{N}$ so large that $(\mathbf{G}^{k'})_{\text{gen}}$ is non-empty (cf. Proposition 5.2).

By general arguments one sees [6] that the codimension of all non-generic strata, i.e. all strata whose type is smaller than $[Z]$, is at least 1.

By Corollary E.2 in Appendix E the non-generic strata in $\mathbf{G}^{3k'}$ have at least codimension 3. Let $k := 3k'$.

- Suppose, the principal fibre bundle $(\mathbf{G}^k)_{\text{gen}}$ were trivial.

Then $(\mathbf{G}^k)_{\text{gen}} \cong (\mathbf{G}^k)_{\text{gen}}/\text{Ad} \times Z \setminus \mathbf{G}$, hence in particular

$$\pi_1^h((\mathbf{G}^k)_{\text{gen}}) \cong \pi_1^h((\mathbf{G}^k)_{\text{gen}}/\text{Ad}) \oplus \pi_1^h(Z \setminus \mathbf{G}). \quad (1)$$

Since because of the compactness of $\mathbf{G}$ the number of non-generic strata in $\mathbf{G}^k$ is finite [26] and each one of the strata is a submanifold of $\mathbf{G}^k$ [6] having codimension bigger or equal 3, we have $\pi_1^h((\mathbf{G}^k)_{\text{gen}}) \cong \pi_1^h(\mathbf{G}^k)$. Consequently, (1) reduces to

$$\pi_1^h(\mathbf{G})^k \cong \pi_1^h(\mathbf{G}^k) \cong \pi_1^h((\mathbf{G}^k)_{\text{gen}}/\text{Ad}) \oplus \pi_1^h(Z \setminus \mathbf{G}).$$

This, however, is contradiction to the assumptions $\pi_1^h(\mathbf{G}) = 1$ and $\pi_1^h(Z \setminus \mathbf{G}) \neq 1$. Hence, $(\mathbf{G}^k)_{\text{gen}}$ is nontrivial. **qed**

⁷We denote the fundamental group not as usual by π_1 , but by π_1^h , in order to avoid confusion with $\pi_k : \mathbf{G}^k \longrightarrow \mathbf{G}^k/\text{Ad}$.

Proposition 9.3 The assumptions of the proposition above are fulfilled, in particular, for all semisimple (simply connected) Lie groups whose decomposition into simple Lie groups contains at least one of the factors A_n , B_n , C_n , D_n , E_6 or E_7 .

Proof It is well-known that among the simple (and simply connected) compact Lie groups exactly the representatives of the series listed above have nontrivial center. [16]
The assumption now follows, because for simply connected $\mathbf{G}$ the order of Z equals $\pi_1^h(Z \setminus \mathbf{G})$ [17] and the center of the direct product of groups equals the direct product of the corresponding centers. **qed**

In particular, we see that $\overline{\mathcal{A}}_{\text{gen}}$ is nontrivial for all $\mathbf{G} = SU(N)$ ($= A_{N-1}$, $N \geq 2$). However, the corresponding problem, e.g., for $\mathbf{G} = SO(N)$ or the prominent case $\mathbf{G} = E_8 \times E_8$ remains unsolved.

We remark that in general for fixed $\mathbf{G}$ the bundles gets “more nontrivial” when k increases. Strictly speaking, we have

Proposition 9.4 For every $\mathbf{G}$ the non-triviality of $(\mathbf{G}^k)_{\text{gen}}$ implies that of $(\mathbf{G}^{k+1})_{\text{gen}}$.

Proof Let k be chosen such that $(\mathbf{G}^k)_{\text{gen}}$ is nontrivial. Suppose there is a section s_{k+1} for $\pi_{k+1} : (\mathbf{G}^{k+1})_{\text{gen}} \longrightarrow (\mathbf{G}^{k+1})_{\text{gen}}/\text{Ad}$.

We get the following commutative diagram

$$\begin{array}{ccccc} (\mathbf{G}^{k+1})_{\text{gen}} & \xleftarrow{\supseteq} & U & \xrightarrow{p_k} & (\mathbf{G}^k)_{\text{gen}} \\ \downarrow \pi_{k+1} & & \downarrow \pi_{k+1}|_U & & \downarrow \pi_k \\ (\mathbf{G}^{k+1})_{\text{gen}}/\text{Ad} & \xleftarrow{\supseteq} & [U] & \xrightarrow{[p_k]} & (\mathbf{G}^k)_{\text{gen}}/\text{Ad} \end{array} \quad .$$

Here $p_k : (\mathbf{G}^{k+1})_{\text{gen}} \longrightarrow (\mathbf{G}^k)_{\text{gen}}$ is the projection onto the first k coordinates and $[p_k]$ is induced in a natural way. Additionally, we defined $U := p_k^{-1}((\mathbf{G}^k)_{\text{gen}})$.

Now we reuse the idea for the proof of Proposition 9.1. First we set $i_k : (\mathbf{G}^k)_{\text{gen}} \longrightarrow U = (\mathbf{G}^k)_{\text{gen}} \times \mathbf{G}$ with $i_k(\vec{g}) := (\vec{g}, e_{\mathbf{G}})$, where the rhs vector is viewed as an element of $\mathbf{G}^{k+1}$. Obviously, i_k is a continuous section for p_k , that additionally – as can be checked quickly – defines a continuous section for $[p_k]$ via $[i_k](\vec{g}) := \pi_{k+1}(i_k(\vec{g}))$.

Finally one sees that $s_k := p_k \circ s_{k+1}|_{[U]} \circ [i_k]$ is a section for π_k . This, however, is a contradiction to the non-triviality of π_k . **qed**

9.3 Conjecture

Let us return again to the proof of Proposition 9.1. There we deduced via φ from the non-triviality of the generic stratum in $\mathbf{G}^k$ that the preimage $\varphi^{-1}((\mathbf{G}^k)_{\text{gen}})$, hence $\overline{\mathcal{A}}_{\text{gen}}$ as well is a nontrivial bundle. But, besides we know that φ is surjective even as a mapping from $\overline{\mathcal{A}}_{\text{gen}}$ to the whole $\mathbf{G}^k$. [13] It seems to be obvious that one can now deduce from the non-existence of a section for π_k over the whole space $\mathbf{G}^k/\text{Ad}$ (and not only over the generic stratum as above) analogously to the case above the non-existence of a global section in $\overline{\mathcal{A}}_{\text{gen}} \longrightarrow \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$. But, the existence of a section for the whole π_k is rather not to be expected because typically in the case of non-commutative structure groups $\mathbf{G}$ the mapping π_k does not define a fibre

bundle. (This can easily be seen because in $\mathbf{G}^k$ there occurs both the orbit [i.e. the fibre] $Z \setminus \mathbf{G}$ and the orbit $\text{pt} = \mathbf{G} \setminus \mathbf{G}$ being never isomorphic. However, this is not a criterion for the non-existence of a section, but simply just an indication.) Hence, one can guess that $\overline{\mathcal{A}}_{\text{gen}}$ is surely nontrivial for non-commutative $\mathbf{G}$, at least as far as π_k possesses no section over the whole $\mathbf{G}^k/\text{Ad}$.

Unfortunately, we were not able to prove this up to now. At one point the proof above uses explicitly the fact that only the generic stratum in $\mathbf{G}^k$ is considered – namely, for the definition of $s_{[\varphi]}$. A continuation of that mapping from the generic elements of $(\mathbf{G}^k)_{\text{gen}}/\text{Ad}$ to the whole $\mathbf{G}^k/\text{Ad}$ is not possible as the next proposition shows:

Proposition 9.5 Let $k \in \mathbb{N}_+$ be some number for that there are both generic and non-generic elements in $\mathbf{G}^k$.

Then there is no continuous mapping $s_\varphi : \mathbf{G}^k \longrightarrow \overline{\mathcal{A}}_{\text{gen}}$, such that $s_{[\varphi]} : \mathbf{G}^k/\text{Ad} \longrightarrow \overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$ with $s_{[\varphi]}([\vec{g}]) := \pi(s_\varphi(\vec{g}))$ is well-defined and that $\varphi \circ s_\varphi = \text{id}_{\mathbf{G}^k}$.

We need the following

Lemma 9.6 Let $k, l \in \mathbb{N}_+$ such that there are generic elements in $\mathbf{G}^l$.

Then we have: $\mathbf{G}$ is abelian iff there is a continuous $f : \mathbf{G}^l \longrightarrow \mathbf{G}^k$ with

- $\vec{g}_1 \sim \vec{g}_2 \implies (\vec{g}_1, f(\vec{g}_1)) \sim (\vec{g}_2, f(\vec{g}_2))$ and
- $Z(\vec{g}) \cap Z(f(\vec{g})) = Z$ for all $\vec{g} \in \mathbf{G}^l$.

Proof • Let $\mathbf{G}$ be abelian. Then, e.g., $f(\vec{g}) = e_{\mathbf{G}}$, $\vec{g} \in \mathbf{G}^l$, fulfills the conditions of the lemma.

- Let $\mathbf{G}$ be non-abelian. Suppose there were such an f . Let $\vec{g}_1, \vec{g}_2 \in \mathbf{G}^l$ be equivalent, i.e., let there exist a $g \in \mathbf{G}$ with $\vec{g}_2 = \vec{g}_1 \circ g$. By assumption there is also a $g' \in \mathbf{G}$ with $(\vec{g}_2, f(\vec{g}_2)) = (\vec{g}_1, f(\vec{g}_1)) \circ g' = (\vec{g}_1 \circ g', f(\vec{g}_1) \circ g')$. Hence, $\vec{g}_1 \circ g = \vec{g}_1 \circ g'$, i.e. $g' = g''g$ for some $g'' \in Z(\vec{g}_1)$. Consequently, $f(\vec{g}_1 \circ g) = f(\vec{g}_2) = f(\vec{g}_1) \circ g' = f(\vec{g}_1) \circ g'' \circ g$. In particular, for all generic $\vec{g}_1$ we have $g'' \in Z$, i.e. $f(\vec{g}_1 \circ g) = f(\vec{g}_1) \circ g$. Since the generic elements by assumption form a dense subset in $\mathbf{G}^l$ (cf. Proposition 5.1) and f is to be continuous, $f(\vec{g}_1 \circ g) = f(\vec{g}_1) \circ g$ has to hold even for all $\vec{g}_1 \in \mathbf{G}^l$ and all $g \in \mathbf{G}$. Let $\vec{g}$ now be a non-generic element in $\mathbf{G}^l$, i.e., let there exist a $g \in Z(\vec{g}) \setminus Z$. But, now $f(\vec{g}) = f(\vec{g} \circ g) = f(\vec{g}) \circ g$, hence $g \in Z(f(\vec{g})) \cap (Z(\vec{g}) \setminus Z) = (Z(\vec{g}) \cap Z(f(\vec{g}))) \setminus Z = \emptyset$. Therefore all $\vec{g} \in \mathbf{G}^l$ are generic in contradiction to the non-commutativity of $\mathbf{G}$. qed

Proof Proposition 9.5

Suppose there exists such an $s_\varphi : \mathbf{G}^k \longrightarrow \overline{\mathcal{A}}_{\text{gen}}$.

1. Let $\vec{g} \in \mathbf{G}^k$ be arbitrary, but fixed. Due to $s_\varphi(\vec{g}) \in \overline{\mathcal{A}}_{\text{gen}}$ there is an $\alpha_{\vec{g}} \subseteq \mathcal{HG}$ with $h_{s_\varphi(\vec{g})}(\alpha_{\vec{g}}) \in (\mathbf{G}^{\#\alpha_{\vec{g}}})_{\text{gen}}$. Since the generic stratum is always open and since together with s_φ and $h_{\alpha_{\vec{g}}}$ also $h_{\alpha_{\vec{g}}} \circ s_\varphi : \mathbf{G}^k \longrightarrow \mathbf{G}^{\#\alpha_{\vec{g}}}$ is continuous, $U_{\vec{g}} := (h_{\alpha_{\vec{g}}} \circ s_\varphi)^{-1}((\mathbf{G}^{\#\alpha_{\vec{g}}})_{\text{gen}})$ defines an open neighbourhood of $\vec{g}$.
2. Varying over all $\vec{g}$ one gets an open covering $\mathcal{U} := \{U_{\vec{g}} \mid \vec{g} \in \mathbf{G}^k\}$ of $\mathbf{G}^k$. Since $\mathbf{G}$ is compact, there are finitely many $\vec{g}_i \in \mathbf{G}^k$ such that $\bigcup_i U_{\vec{g}_i} = \mathbf{G}^k$. Let now α' be the set (the tuple, respectively) of all these $\alpha_{\vec{g}_i}$.
3. We define $f := h_{\alpha'} \circ s_\varphi : \mathbf{G}^k \longrightarrow \mathbf{G}^{\#\alpha'}$ and – recall $\varphi \equiv h_\alpha$ –

$$f' := (h_\alpha \circ s_\varphi, h_{\alpha'} \circ s_\varphi) \equiv (\text{id}_{\mathbf{G}^k}, f) : \mathbf{G}^k \longrightarrow \mathbf{G}^{k+\#\alpha'}.$$

We have:

- f is continuous.
- Let $\vec{g}', \vec{g}'' \in \mathbf{G}^k$ with $\vec{g}' \sim \vec{g}''$. From that, due to the assumed well-definedness of $s_{[\varphi]}$, $s_{\varphi}(\vec{g}') \sim s_{\varphi}(\vec{g}'')$ w.r.t. $\overline{\mathcal{G}}$. Hence, in particular $(\vec{g}', f(\vec{g}')) = f'(\vec{g}') \sim f'(\vec{g}'') = (\vec{g}'', f(\vec{g}''))$.
- $Z(f(\vec{g})) = Z$ for all $\vec{g} \in \mathbf{G}^k$.

Let $\vec{g} \in \mathbf{G}^k$. Then there is an i with $\vec{g} \in U_{\vec{g}_i}$. Thus, $h_{\alpha_{\vec{g}_i}}(s_{\varphi}(\vec{g})) \in (\mathbf{G}^{\#\alpha_{\vec{g}_i}})_{\text{gen}}$, hence $f(\vec{g}) = h_{\alpha'} \circ s_{\varphi}(\vec{g}) \in (\mathbf{G}^{\#\alpha'})_{\text{gen}}$ due to $\alpha_{\vec{g}_i} \subseteq \alpha'$.

Due to $Z \subseteq Z(\vec{g}) \cap Z(f(\vec{g})) \subseteq Z(f(\vec{g})) = Z$, f fulfills all assumptions of the preceding lemma, i.e., $\mathbf{G}$ is abelian in contradiction to the supposition. **qed**

Despite these obstacles we close this section with an even stronger

Conjecture 9.7 $\overline{\mathcal{A}}_{\text{gen}}$ is nontrivial for every non-commutative $\mathbf{G}$.

Perhaps, there is even for every non-commutative $\mathbf{G}$ a k such that $(\mathbf{G}^k)_{\text{gen}}$ is nontrivial.

10 Discussion

We summarize the results of this paper on the structure of the generic stratum of $\overline{\mathcal{A}}$, noting that the assertions of the following theorem are completely independent of the base manifold M :

Theorem 10.1

1. $\overline{\mathcal{A}}_{\text{gen}}$ has the induced Haar measure 1.
2. $\overline{\mathcal{A}}_{\text{gen}}$ is a μ_0 -almost globally trivial principal $\overline{\mathcal{G}}$ -fibre bundle with structure group $\mathbf{B}_Z \backslash \overline{\mathcal{G}}$.
3. $\overline{\mathcal{A}}_{\text{gen}}$ is globally trivial for abelian $\mathbf{G}$.
4. $\overline{\mathcal{A}}_{\text{gen}}$ is not globally trivial for nonabelian, simply connected $\mathbf{G}$ with nontrivial center.

Here $\mathbf{B}_Z \subseteq \overline{\mathcal{G}}$ is the set of all constant, center-valued gauge transforms.

Hence, the Gribov problem – well-known in the case of regular (Sobolev) connections for a long time – appears in the Ashtekar approach as well. However, we could refine the statement substantially: The non-triviality is now concentrated on a zero subset. Just this fact has large physical importance – it justifies the definition of the induced Haar measure on $\overline{\mathcal{A}}/\overline{\mathcal{G}}$ by the image measure of the corresponding measure on $\overline{\mathcal{A}}$. Actually, there are two possibilities for the choice of such a measure.⁸

Let X be some topological space equipped with a measure μ and let G be some topological group acting on X . What should the corresponding measure μ_G on the orbit space X/G look like? On the one hand, one could simply define $\mu_{G,1}(U) := \pi_*\mu(U) \equiv \mu(\pi^{-1}(U))$ for all measurable $U \subseteq X/G$, i.e. use the image measure w.r.t. the canonical projection $\pi : X \rightarrow X/G$. On the other hand, one could perform a kind of Faddeev-Popov transformation: Let us assume that X can be written as a disjoint union of certain sets V and that each V equals $V/G \times G_V \backslash G$ where G_V characterizes the type of orbits on V . Then one could define the measure of a set U that w.l.o.g. is contained in one of these V/G naively by

$$\mu_{G,2}(U) := \mu(\pi^{-1}(U)) \nu(G_V) \quad (2)$$

⁸For an earlier discussion see [13].

where ν somehow measures the “size” of the stabilizer G_V in G . (The measure of a general U can then be defined via $\mu_{G,2}(U) := \sum_V \mu_{G,2}(U \cap (V/G))$.) In contrast to the first method, here the orbit space and not the total space is regarded to be primary: If the measure is uniformly distributed over all points of the total space, the image measure on the orbits would in the first case no longer be uniformly distributed; the weighting of the orbits comes along according to their size. But, in the second case the uniform distribution remains, i.e. the group degrees of freedom do not play any rôle in Faddeev-Popov context. That the equation (2) above can indeed be seen as a Faddeev-Popov transformation will be clear by means of a small rearrangement. Namely, we have⁹

$$\mu(\pi^{-1}(U)) = \frac{1}{\nu(G_V)} \mu_{G,2}(U),$$

hence

$$\pi_*\mu = \Delta \odot \mu_{G,2} \quad \text{with} \quad \Delta : \begin{array}{ccc} X & \longrightarrow & \widehat{\mathbb{R}} \\ x & \longmapsto & \frac{1}{\nu(\text{Stab}(x))} \end{array} . \quad (3)$$

Thus, $\frac{1}{\nu(G_V)} = \Delta$ is nothing but the Faddeev-Popov determinant.

But, what does this mean for our concrete problem $X = \overline{\mathcal{A}}$, $G = \overline{\mathcal{G}}$ and $\mu = \mu_0$? Since the stabilizer of a connection in the generic stratum is minimal, Δ is maximal on $\overline{\mathcal{A}}_{\text{gen}}$. Moreover, Δ has to be constant on the whole $\overline{\mathcal{A}}_{\text{gen}}$. Since we can assume that Δ is not identically 0, we get the measure $\mu_{0,2}$ on $\overline{\mathcal{A}}_{\text{gen}}/\overline{\mathcal{G}}$ directly from (3). Hence, we are left with the nongeneric strata only. We know already that the stabilizer of a connection is isomorphic to the corresponding holonomy centralizer. But, typically this subgroup of $\mathbf{G}$ has a higher dimension than the center has, i.e. its measure w.r.t. ν should be infinite. Hence, Δ would vanish on the nongeneric connections, and a complete determination of $\mu_{0,2}$ via (3) is no longer possible. The simplest way out would be of course to give the nongeneric strata simply the $\mu_{0,2}$ -measure 0. This is plausible, if one takes into account that, on the one hand, in the case of (sufficiently smooth) actions of Lie groups on manifolds the nonmaximal strata have lower dimension than the maximal stratum has even after being projected down to the orbit space, i.e. they can be regarded as zero subsets, and, on the other hand, the measure on $\overline{\mathcal{A}}/\overline{\mathcal{G}}$ could be defined using the projections $\pi_v : \overline{\mathcal{A}}/\overline{\mathcal{G}} \longrightarrow \mathbf{G}^k/\text{Ad}$. Nevertheless, it remains for the time being unclear, whether one excludes this way perhaps physically interesting phenomena. However, the danger is relatively small. The measure $\mu_{0,2}$ is, of course, not yet the “dynamical” measure, but simply a kind of “kinematical” measure. This serves only as a – in a certain sense natural – background measure by that means using the dynamics of the system the “physical” measure can be constructed. One could even argue that this kinematical measure should contain no dynamical information *at all*. Using this point of view – and using the arguments above on the measures of nongeneric strata – we think it is meaningful to give these nongeneric strata in $\overline{\mathcal{A}}/\overline{\mathcal{G}}$ the induced Haar measure 0.

Therewith we realize that both possibilities above for defining a measure on the orbit space are equivalent in the case of $\overline{\mathcal{A}}/\overline{\mathcal{G}}$. Here Δ is constant up to a zero subset, hence identical 1, i.e., we have $\mu_{0,1} = \pi_*\mu_0 = \Delta \odot \mu_{0,2} = \mu_{0,2}$. Additionally, we see that we can restrict ourselves to an almost global trivialization of $\overline{\mathcal{A}}_{\text{gen}}$ when integrating. Consequently, the Gribov problem appearing for certain $\mathbf{G}$ is irrelevant, e.g., for the calculation of expectation values w.r.t. μ_0 . Moreover: This statement is true even for all measures that are absolutely continuous w.r.t.

⁹We drop – in contrast to the Faddeev-Popov strategy in the introduction – the (fixed) measure $\nu'(G)$ of the totally acting group.

μ_0 . Therefore, the next step in this context should be an investigation of the structure of physically interesting measures.

The idea of using homotopy arguments for the proof of the non-triviality on the Lie group level is due to Lorenz Schwachhöfer. Moreover, the author thanks Detlev Buchholz, Hartmann Römer, Gerd Rudolph and Matthias Schmidt for inspiring discussions.

Appendix

A Group Isomorphism of the Two Normalizers

In Section 2 we dealt with structure groups of the strata. As in the case of the stabilizer of a connection we could describe each of these groups using by far simpler structures in the underlying Lie group $\mathbf{G}$. We saw that

$$\mathbf{B}(\overline{A}) \setminus N(\mathbf{B}(\overline{A})) \text{ and } Z(\mathbf{H}_{\overline{A}}) \setminus N(Z(\mathbf{H}_{\overline{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\overline{A}}))$$

are homeomorphic. In this appendix we are going to discuss whether these groups are isomorphic even as topological groups.

In order to reduce the size of the expressions in what follows, we assume w.l.o.g. that the connection $\overline{A} \in \overline{\mathcal{A}}$ being under consideration has the property that $h_{\overline{A}}(\gamma_x) = e_{\mathbf{G}}$ for all $x \in M$ where γ_x is as usual some fixed path from m to x and γ_m is trivial. This, indeed, is no restriction because every $\overline{A}' \in \overline{\mathcal{A}}$ is gauge equivalent to such an $\overline{A}$. For this, one would simply set $\overline{g} := (h_{\overline{A}'}(\gamma_x)^{-1})_{x \in M} \in \overline{\mathcal{G}}$ and $\overline{A} := \overline{A}' \circ \overline{g}$.

As we noticed in the main text already, we will restrict ourselves to so-called “reasonable” isomorphisms.

1. We look only for isomorphisms between

$$\mathbf{B}(\overline{A}) \setminus N(\mathbf{B}(\overline{A})) \text{ and } Z(\mathbf{H}_{\overline{A}}) \setminus N(Z(\mathbf{H}_{\overline{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\overline{A}}))$$

that are induced by an isomorphism

$$\psi : N(\mathbf{B}(\overline{A})) \longrightarrow N(Z(\mathbf{H}_{\overline{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\overline{A}}))$$

between the two non-factorized spaces. This means, such a factor isomorphism has to be a continuation of the natural isomorphism between the base centralizer and the holonomy centralizer, hence fulfill $\psi(\mathbf{B}(\overline{A})) = Z(\mathbf{H}_{\overline{A}}) \times \bigtimes_{x \neq m} \{e_{\mathbf{G}}\}$.

2. We denote the mapping, that one gets by concatenation of ψ and of the corresponding projection to the x -component of the image space, by ψ_x , $x \in M$. For a “reasonable” isomorphism ψ we demand

- a) $\psi_m \equiv \pi_m : N(\mathbf{B}(\overline{A})) \longrightarrow N(Z(\mathbf{H}_{\overline{A}}))$ and
- b) $\psi_x(\overline{g})$ depends only on the values of $\overline{g}$ in x and m .

We think viewing at Proposition 2.2 these restrictions are natural. We neglect only “wild” isomorphisms, i.e. mappings that mix the points of M .

Now, let ψ be a “reasonable” isomorphism. We fix a point $x \neq m$ and investigate, how the projection ψ_x of ψ to the point x has to look like.

Since ψ is to be a “reasonable” homomorphism, ψ_x is a map from (g_m, g_x) to $\psi_x(\bar{g}) \equiv \psi_x(g_m, g_x)$. By Proposition 2.2 every $\bar{g} \in N(\mathbf{B}(\bar{A}))$ is just determined by the values of $g_m \in N(Z(\mathbf{H}_{\bar{A}}))$ and of $z_x \in Z(Z(\mathbf{H}_{\bar{A}}))$: we have $g_x = z_x g_m$. Hence, ψ_x is well-defined iff¹⁰

$$\psi_x(g, zg) \in Z(Z(\mathbf{H}_{\bar{A}})) \text{ for all } g \in N(Z(\mathbf{H}_{\bar{A}})) \text{ and } z \in Z(Z(\mathbf{H}_{\bar{A}})). \quad (4)$$

The homomorphism property implies $\psi(\bar{g}_1)\psi(\bar{g}_2) = \psi(\bar{g}_1\bar{g}_2)$ for all $\bar{g}_i \in N(\mathbf{B}(\bar{A}))$, hence

$$\psi_x(g_1g_2, z_1g_1z_2g_2) = \psi_x(g_1, z_1g_1)\psi_x(g_2, z_2g_2) \text{ for all } g_i \in N(Z(\mathbf{H}_{\bar{A}})) \text{ and } z_i \in Z(Z(\mathbf{H}_{\bar{A}})). \quad (5)$$

Now, we define

$$\chi(z) := \psi_x(1, z) \text{ for } z \in Z(Z(\mathbf{H}_{\bar{A}}))$$

and

$$\varphi(g) := \psi_x(g, g) \text{ for } g \in N(Z(\mathbf{H}_{\bar{A}})).$$

Obviously $\chi : Z(Z(\mathbf{H}_{\bar{A}})) \rightarrow Z(Z(\mathbf{H}_{\bar{A}}))$ and $\varphi : N(Z(\mathbf{H}_{\bar{A}})) \rightarrow Z(Z(\mathbf{H}_{\bar{A}}))$ are continuous (hence smooth) homomorphisms and we have

$$\psi_x(g, zg) = \chi(z)\varphi(g).$$

χ is even an automorphism of $Z(Z(\mathbf{H}_{\bar{A}}))$ because χ is per constr. an injective Lie morphism.¹¹ The injectivity of χ here is a consequence of our assumption that ψ_m is trivial and $\psi_x(\bar{g})$ does not depend on $g_{x'}$, $x' \neq x, m$.

Now let $g \in N(Z(\mathbf{H}_{\bar{A}}))$ with $\varphi(g) \in Z(Z(Z(\mathbf{H}_{\bar{A}}))) = Z(\mathbf{H}_{\bar{A}})$. Due to the bijectivity of χ we have exactly for those g that $\psi_x(g, zg) = \chi(z)\varphi(g) = \varphi(g)\chi(z) = \psi_x(g, gz)$ for all $z \in Z(Z(\mathbf{H}_{\bar{A}}))$. This implies that $zg = gz$, i.e. $g \in Z(Z(Z(\mathbf{H}_{\bar{A}}))) = Z(\mathbf{H}_{\bar{A}})$. Hence we get

$$\varphi^{-1}(Z(\mathbf{H}_{\bar{A}})) \subseteq Z(\mathbf{H}_{\bar{A}}). \quad (6)$$

Our assumption $\psi(\mathbf{B}(\bar{A})) = Z(\mathbf{H}_{\bar{A}}) \times \bigtimes_{x \neq m} \{e_{\mathbf{G}}\}$ implies now¹² $\varphi(Z(\mathbf{H}_{\bar{A}})) = \{e_{\mathbf{G}}\}$. This again yields $\ker \varphi \subseteq \varphi^{-1}(Z(\mathbf{H}_{\bar{A}})) \subseteq Z(\mathbf{H}_{\bar{A}}) \subseteq \ker \varphi$, hence

$$\ker \varphi = Z(\mathbf{H}_{\bar{A}}). \quad (7)$$

Therefore we have

$$Z(\mathbf{H}_{\bar{A}}) \setminus N(Z(\mathbf{H}_{\bar{A}})) \cong \text{im } \varphi \subseteq Z(Z(\mathbf{H}_{\bar{A}})). \quad (8)$$

This, however, cannot always be fulfilled. Let, e.g., be $\mathbf{G} = SU(2)$ and $\bar{A}$ be generic. Then $Z(\mathbf{H}_{\bar{A}}) = Z(SU(2)) = \mathbb{Z}_2$ and $Z(Z(\mathbf{H}_{\bar{A}})) = N(Z(\mathbf{H}_{\bar{A}})) = SU(2)$. We are looking now for a homomorphism $\varphi : SU(2) \rightarrow SU(2)$ with $\ker \varphi = \mathbb{Z}_2$. By the homomorphism theorem $SO(3) \cong SU(2)/\mathbb{Z}_2 \cong \text{im } \varphi$ is a subgroup of $SU(2)$. This is a contradiction.¹³ Hence, in general, there is *no* “reasonable” isomorphism of topological groups between $\mathbf{B}(\bar{A}) \setminus N(\mathbf{B}(\bar{A}))$ and $Z(\mathbf{H}_{\bar{A}}) \setminus N(Z(\mathbf{H}_{\bar{A}})) \times \bigtimes_{x \neq m} Z(Z(\mathbf{H}_{\bar{A}}))$.

Finally, we discuss two special cases.

¹⁰In what follows we in general drop the index m in g_m and the index x in z_x .

¹¹In general every injective Lie morphism $f : \mathbf{G} \rightarrow \mathbf{G}$ is already a Lie isomorphism, if $\mathbf{G}$ is a compact Lie group. This one sees as follows: $\text{im } f$ is compact as a continuous image of a compact set, hence closed. Since the image of a homomorphism in general is a subgroup of the target space, $\text{im } f$ is Lie subgroup. By the homomorphism theorem [17] we have $\text{im } f \cong \mathbf{G}/\ker f \cong \mathbf{G}$. Hence, $\text{im } f$ as a subgroup of $\mathbf{G}$ has the same dimension and the same number of connected components as $\mathbf{G}$, and thus is equal to $\mathbf{G}$. Therefore f is continuous and bijective, hence a homeomorphism, hence a Lie isomorphism.

¹²Note that $\mathbf{B}(\bar{A})$ due to the special choice of the $h_{\bar{A}}(\gamma_x)$ consists just of the constant $Z(\mathbf{H}_{\bar{A}})$ -valued gauge transforms.

¹³ $SO(3)$ as (an isomorphic image of) a subgroup of $SU(2)$ having the identical dimension and the same number of connected components has to be even equal $SU(2)$. But, this is impossible, because $SO(3)$ and $SU(2)$ are non-isomorphic.

- $\chi(z) = z$ and $\varphi(g) = g$.

The resulting mapping $\psi_x(g, zg) = zg$ just corresponds to the restriction Ψ_0 of the identical map on $\overline{\mathcal{G}}$. This, however, gives a group isomorphism only if φ is indeed a map from $N(Z(\mathbf{H}_{\overline{A}}))$ to $Z(Z(\mathbf{H}_{\overline{A}}))$, i.e., these two spaces are equal.

This criterion is fulfilled for instance in the generic stratum. And indeed, in this case Ψ_0 is a group isomorphism between $N(\mathbf{B}(\overline{A}))$ and $N(Z(\mathbf{H}_{\overline{A}})) \times \prod_{x \neq m} Z(Z(\mathbf{H}_{\overline{A}}))$. Nevertheless, Ψ_0 factorizes by condition (7) only then to an isomorphism of the quotient groups if $Z(\mathbf{G}) = Z(\mathbf{H}_{\overline{A}}) = \ker \varphi$ equals $\{e_{\mathbf{G}}\}$.

In the minimal stratum Ψ_0 is in general no longer an isomorphism because at least for non-abelian $\mathbf{G}$ (i.e., if $\overline{A}_{\text{gen}} \neq \overline{A}_{t_{\min}}$), $N(Z(\mathbf{H}_{\overline{A}})) = \mathbf{G}$ is not equal $Z(Z(\mathbf{H}_{\overline{A}})) = Z(\mathbf{G})$.

- $\chi(z) = z$ and $\varphi(g) = e_{\mathbf{G}}$.

The resulting mapping $\psi_x(g, zg) = z$ corresponds here to the homeomorphism Ψ_1 from Corollary 2.3. In order to turn ψ into a homomorphism, by condition (7), $N(Z(\mathbf{H}_{\overline{A}})) = \ker \varphi = Z(\mathbf{H}_{\overline{A}})$ has to hold.

This condition is fulfilled in the minimal stratum. (Then, as can be easily checked, Ψ_1 is indeed a group isomorphism.)

On the other hand, Ψ_1 is no isomorphism for generic $\overline{A}$ in the non-abelian case. This is clear, because there we have $N(Z(\mathbf{H}_{\overline{A}})) = \mathbf{G}$, but $Z(\mathbf{H}_{\overline{A}}) = Z(\mathbf{G})$.

We see again that it is in many cases impossible to find a group isomorphism that additionally does not depend explicitly on the respective stratum containing $\overline{A}$.

B Stratification of $SU(2)^k$

Every $SU(2)$ -matrix A can be written uniquely as $A = \begin{pmatrix} a & b \\ -b^* & a^* \end{pmatrix}$ where $a, b \in \mathbb{C}$ are complex numbers fulfilling $|a|^2 + |b|^2 = 1$. Alternatively such a matrix can be seen as a quaternion $A = a + bj \in \mathbb{H}$. In this case we also describe A by $a_0 + a_1i + a_2j + a_3k$ or $a_0 + \vec{a}$ with $\sum a_i^2 = 1$, $a_i \in \mathbb{R}$. We have $SU(2) \cong S^3 \subseteq \mathbb{R}^4$.

B.1 Adjoint Action on $SU(2)$

Let $A, C \in SU(2)$ with $A = a_0 + a_1i + a_2j + a_3k$ and $C = c_0 + c_1i + c_2j + c_3k$. It is easy to check that the adjoint action in terms of quaternions is

$$C^+AC = a_0 + \vec{a} + 2(\langle \vec{a}, \vec{c} \rangle \vec{c} - \langle \vec{c}, \vec{c} \rangle \vec{a} + c_0(\vec{a} \times \vec{c})) = a_0 + \vec{a} + 2(c_0(\vec{a} \times \vec{c}) - \vec{c} \times (\vec{a} \times \vec{c})).$$

Here, $\langle \cdot, \cdot \rangle$ is the canonical scalar product on $\mathbb{R}^3$. We determine the stabilizer of A .

We have $C^{-1}AC = C^+AC = A + 2(\langle \vec{a}, \vec{c} \rangle \vec{c} - \langle \vec{c}, \vec{c} \rangle \vec{a} + c_0(\vec{a} \times \vec{c}))$, hence

$$C \in Z(A) \iff C^{-1}AC = A \iff \langle \vec{a}, \vec{c} \rangle \vec{c} - \langle \vec{c}, \vec{c} \rangle \vec{a} + c_0(\vec{a} \times \vec{c}) = 0. \quad (9)$$

There are two cases:

1. $\vec{a} = 0$, i.e. $A = \pm \mathbf{1}$.

Clearly, the rhs of (9) is true for all $C \in SU(2)$, i.e. $Z(A) = SU(2)$.

2. $\vec{a} \neq 0$, i.e. $A \neq \pm \mathbf{1}$.

Let $C \in Z(A)$. Multiplying the rhs of (9) by $\vec{a}$ we get $\langle \vec{a}, \vec{c} \rangle \langle \vec{c}, \vec{a} \rangle - \langle \vec{c}, \vec{c} \rangle \langle \vec{a}, \vec{a} \rangle = 0$. This implies due to $\vec{a} \neq 0$ that $\vec{c} = \mu \vec{a}$ for some $\mu \in \mathbb{R}$. Conversely, every such C is indeed a solution. One easily sees $Z(A) \cong U(1)$.

In the following we interpret a subset X of the three-dimensional ball B^3 also as a subset $X := \{A = a_0 + \vec{a} \in SU(2) \mid \vec{a} \in X\}$ of $SU(2)$.

Lemma B.1 For $A = a_0 + \vec{a} \in SU(2)$ we have $Z(A) = \begin{cases} B^3 & \text{for } a_0^2 = 1 \\ \mathbb{R}\vec{a} \cap B^3 & \text{for } a_0^2 \neq 1 \end{cases}$.

Since every $SU(2)$ -matrix can be diagonalized, there is a diagonal matrix in every orbit

Proposition B.2 Every orbit $A \circ SU(2)$ w.r.t. the adjoint action of $SU(2)$ on itself contains a point of the form $a_0 + \sqrt{1 - a_0^2} \mathbf{i}$. We have $SU(2)/\text{Ad} \cong [-1, 1]$ by $[A] \mapsto \frac{1}{2}\text{tr}A$.
The orbits are the small spheres with constant real part a_0 .

B.2 Adjoint Action on $SU(2)^2$

A crucial point for the investigation of gauge orbit types has been the finiteness lemma for centralizers [13], i.e. every centralizer can be represented as the centralizer of finitely many elements. When we have dealt with the generic stratum we have seen that it is important to generate this way the center of the structure group. How many elements do we need at least for that procedure?

Lemma B.3 We have $Z = \{\pm \mathbf{1}\} \equiv \mathbb{Z}_2$.

Proof $Z = \bigcap_{A \in SU(2)} Z(A) = B^3 \cap \bigcap_{\vec{a} \in B^3} \mathbb{R}\vec{a} = \{\vec{0}\} \equiv \{\pm \mathbf{1}\}$ by Lemma B.1. **qed**

Obviously no single element of $SU(2)$ generates the whole center, but already two elements are sufficient. We only have to guarantee that their centralizers have trivial intersection.

Proposition B.4 There are three orbit types on $SU(2) \times SU(2)$.

Explicitly we have for $A, B \in SU(2)$:

1. Type $[SU(2)]$
 $Z(A, B) = B^3$ iff $Z(A) = Z(B) = B^3$.
2. Type $[U(1)]$
 $Z(A, B) = \mathbb{R}\vec{c} \cap B^3$ iff
 - a) one centralizer equals B^3 and one equals $\mathbb{R}\vec{c} \cap B^3$ or
 - b) two centralizers equal $\mathbb{R}\vec{c} \cap B^3$.
3. Type $[\mathbb{Z}_2]$ (generic elements)
 $Z(A, B) = \{\vec{0}\}$ iff $Z(A) = \mathbb{R}\vec{a} \cap B^3$ and $Z(B) = \mathbb{R}\vec{b} \cap B^3$ where $\vec{a}$ and $\vec{b}$ are non-collinear.

The dimensions of the respective strata are:

- Type $[SU(2)]$: 0;
- Type $[U(1)]$: 3 (case 2.a)) or 4 (case 2.b));
- Type $[\mathbb{Z}_2]$: 6.

Clearly, $(SU(2)^2)_{\text{gen}}$ is open and dense in $SU(2)^2$. The orbits in the generic stratum are isomorphic to $SU(2)/\mathbb{Z}_2$, i.e. are three-dimensional. Hence the quotient space $(SU(2)^2)_{\text{gen}}/\text{Ad}$ is three-dimensional.

Next, we shall find a continuous section in the generic stratum of $SU(2)^2$. What could be a “natural” element describing an orbit $[(A, B)]$? Let there be given $(A, B) \in (SU(2)^2)_{\text{gen}}$. First we are free to use a matrix C for diagonalizing the first component A . We get (C^+AC, C^+BC) . It remains the freedom to act with a second matrix Δ_β , however, keeping C^+AC invariant. Hence, Δ_β has to be a diagonal matrix. On the other hand, Δ_β has to transform the matrix C^+BC . Otherwise, C^+BC would be a diagonal matrix in contradiction to $Z(A) \cap Z(B) = \{\vec{0}\}$. Hence, by an appropriate choice of Δ_β we can make the secondary diagonal of $(C\Delta_\beta)^+B(C\Delta_\beta)$ real. Explicitly we get:

Proposition B.5 In every generic orbit there is a unique element of the form

$$\left(\begin{pmatrix} \lambda & 0 \\ 0 & \lambda^* \end{pmatrix}, \begin{pmatrix} x & \sqrt{1-|x|^2} \\ -\sqrt{1-|x|^2} & x^* \end{pmatrix} \right)$$

where $|\lambda| = 1$, $\text{Im } \lambda > 0$ and $|x| < 1$. We call such an element standard form of the orbit (or its elements).

Conversely, every such element defines a unique generic orbit.

Furthermore the mapping $\pi_F : (SU(2)^2)_{\text{gen}} \longrightarrow (SU(2)^2)_{\text{gen}}$ assigning to every element its standard form is continuous.

Explicitly, we have for the standard form of $(A, B) = (a_0 + \vec{a}, b_0 + \vec{b})$:

$$\begin{aligned} \lambda &= a_0 + \|\vec{a}\|\mathbf{i} \\ x &= b_0 + \frac{\langle \vec{a}, \vec{b} \rangle}{\|\vec{a}\|}\mathbf{i}, \end{aligned}$$

where $\langle \cdot, \cdot \rangle$ is again the canonical scalar product on $\mathbb{R}^3$.

On the level of quaternions the element above can be written as $(\lambda, x + \sqrt{1-|x|^2} \mathbf{j})$.

Proof • Existence

Let $A = a_0 + \vec{a} = a_0 + a_1\mathbf{i} + a_2\mathbf{j} + a_3\mathbf{k} \neq \pm \mathbf{1}$. Define¹⁴

$$\varepsilon := \frac{a_1}{\|\vec{a}\|} \quad \text{and} \quad \delta := \frac{a_2 + a_3\mathbf{i}}{\sqrt{a_2^2 + a_3^2}}$$

as well as

$$C := \frac{1}{\sqrt{2}} \begin{pmatrix} \mathbf{i}\sqrt{1+\varepsilon} & \delta\sqrt{1-\varepsilon} \\ -\delta^*\sqrt{1-\varepsilon} & -\mathbf{i}\sqrt{1+\varepsilon} \end{pmatrix}.$$

One easily checks $C^+(A, B)C = \left(\begin{pmatrix} \lambda & 0 \\ 0 & \lambda^* \end{pmatrix}, \tilde{B} \right)$ with an appropriate matrix $\tilde{B}$, where $|\lambda| = 1$ and $\text{Im } \lambda > 0$.¹⁵

Afterwards we choose a $\beta \in \mathbb{C}$ with

$$\beta^2 = \frac{\tilde{b}_2 + \tilde{b}_3\mathbf{i}}{\sqrt{\tilde{b}_2^2 + \tilde{b}_3^2}}.$$

Here let $\tilde{b}_i$ be as usual the quaternionic components of $\tilde{B}$. Note that the denominator above is always nonzero because $\tilde{B}$ cannot be a diagonal matrix.

Now, on the one hand, the diagonal matrix $\Delta_\beta := \begin{pmatrix} \beta & 0 \\ 0 & \beta^* \end{pmatrix}$ commutes with C^+AC and, on the other hand, the secondary diagonal in $\Delta_\beta^+ \tilde{B} \Delta_\beta$ is real and positive in the upper right corner, thus, in particular, nonzero. Hence $(C\Delta_\beta)^+(A, B)(C\Delta_\beta)$ is of the desired type.

¹⁴ δ can be chosen arbitrarily with norm 1 if $a_2 = a_3 = 0$.

¹⁵Note that $\text{Im } \lambda = 0$ is impossible because otherwise $\lambda = \pm 1$, i.e. $A = \pm \mathbf{1}$.

Furthermore, one checks that λ and x depend indeed in the given manner on A and B .¹⁶

- Uniqueness¹⁷

Suppose, there were two such elements $(A_i, B_i) = (\lambda_i, x_i + \sqrt{1 - |x_i|^2} \mathbf{j})$ fulfilling the conditions above. Then there is a $C \in SU(2)$ with $C^+(A_1, B_1)C = (A_2, B_2)$.

$$- C^+ A_1 C = A_2$$

Since conjugate quaternions have always the same real part, we have $\operatorname{Re} \lambda_1 = \operatorname{Re} \lambda_2$. Hence, $\lambda_1 = \lambda_2$ oder $\lambda_1 = \lambda_2^*$. Since $\operatorname{Im} \lambda_i > 0$ by assumption, we get $\lambda_1 = \lambda_2$, thus $A_1 = A_2$.

Moreover, that is why C is in $Z(A_1)$ and equals $\mu \in \mathbb{C}$ with $|\mu| = 1$.

$$- C^+ B_1 C = B_2$$

We have

$$\begin{aligned} x_2 + \sqrt{1 - |x_2|^2} \mathbf{j} &= B_2 \\ &= C^+ B_1 C \\ &= \mu^* (x_1 + \sqrt{1 - |x_1|^2} \mathbf{j}) \mu \\ &= x_1 + \sqrt{1 - |x_1|^2} \mu^* \mu^* \mathbf{j}, \end{aligned}$$

thus first $x_1 = x_2$. Therefore the expressions containing the roots are equal, and due to $|x_i| < 1$ we have $(\mu^*)^2 = 1$, i.e. $\mu = \pm 1$.

Thus, $C = \pm \mathbf{1} \in Z$ and hence $(A_1, B_1) = (A_2, B_2)$.

- Since we assumed $|x| < 1$, every element in the proposition above defines an orbit in the generic stratum.
- The continuity of π_F is clear because of $\|\vec{a}\| \neq 0$ in the generic stratum.¹⁸ **qed**

We denote the space of all standard forms by F . Then F is homeomorphic to the product of the upper open semicircle of $U(1)$ (λ -part) and the upper open hemisphere of S^2 (x -part), hence is homeomorphic to $\mathbb{R}^3$.

Proposition B.6 We have $F \cong (SU(2)^2)_{\text{gen}}/\text{Ad}$.

Proof Let $f : F \longrightarrow (SU(2)^2)_{\text{gen}}/\text{Ad}$ be the concatenation of the embedding ι of F into $(SU(2)^2)_{\text{gen}}$ and the canonical projection π_2 :

$$\begin{array}{ccc} F & \xrightleftharpoons[\pi_F]{\iota} & (SU(2)^2)_{\text{gen}} \\ f \downarrow & \swarrow \pi_2 & \\ (SU(2)^2)_{\text{gen}}/\text{Ad} & & \end{array}$$

- f is bijective by Proposition B.5.

¹⁶More general, for the action of $C\Delta_\beta$ on a matrix $M = m_0 + \vec{m}$ we have:

$$(C\Delta_\beta)^+ M (C\Delta_\beta) = m_0 + \frac{\langle \vec{a}, \vec{m} \rangle}{\|\vec{a}\|} \mathbf{i} + \frac{\langle \vec{a} \times \vec{b}, \vec{a} \times \vec{m} \rangle}{\|\vec{a} \times \vec{b}\| \|\vec{a}\|} \mathbf{j} + \frac{\langle \vec{a} \times \vec{b}, \vec{m} \rangle}{\|\vec{a} \times \vec{b}\|} \mathbf{k}.$$

¹⁷Here, all expressions are quaternionic.

¹⁸But, note that the map $A \longmapsto C$ itself is *not* continuous. This can be seen in the special case that A goes to a diagonal matrix, i.e. for $a_2, a_3 \rightarrow 0$ and (here) $a_1 < 0$. Then namely $\varepsilon \rightarrow -1$, i.e., C goes as $\frac{a_2 + a_3 \mathbf{i}}{\sqrt{a_2^2 + a_3^2}} \mathbf{j}$, hence is divergent.

- f is continuous as a concatenation of continuous maps.
- f^{-1} is continuous, because at least locally (around every point) there is a continuous section s_2 for π_2 such that locally $f^{-1} = \pi_F \circ s_2$ which implies the local continuity. However, then f^{-1} is globally continuous. **qed**

Consequently, the generic stratum of $SU(2)^2$ is homeomorphic to $\mathbb{R}^3 \times SO(3)$ because $SU(2)/\mathbb{Z}_2 \cong SO(3)$.

We remark that the total orbit space $SU(2)^2/\text{Ad}$ is homeomorphic to the three-ball B^3 where the singular strata are simply its boundary S^2 .

B.3 Adjoint Action on $SU(2)^3$

We will show here that the adjoint action on $SU(2)^3$ leads to a nontrivial generic stratum. The argument here is again a pure homotopy argument as in the proof of the more general Proposition 9.2. But, here we will explicitly describe the strata on $SU(2)^3$ and show that the non-generic strata have codimension 4. (By the way, one easily recognizes that the codimension of the non-generic strata on $SU(2)^k$ equals $2(k-1)$.)

Proposition B.7 On $SU(2) \times SU(2) \times SU(2)$ there are three orbit types.

Explicitly we have for $A, B, C \in SU(2)$:

1. Type $[SU(2)]$
(Dimension 0) $Z(A, B, C) = B^3$ iff $Z(A) = Z(B) = Z(C) = B^3$.
2. Type $[U(1)]$
 $Z(A, B, C) = \mathbb{R}\vec{d} \cap B^3$ iff
 - a) (Dimension 3) two centralizers equal B^3 and one equals $\mathbb{R}\vec{d} \cap B^3$
or
 - b) (Dimension 4) one centralizer equals B^3 and two equal $\mathbb{R}\vec{d} \cap B^3$
or
 - c) (Dimension 5) three centralizers equal $\mathbb{R}\vec{d} \cap B^3$.
3. Type $[\mathbb{Z}_2]$ (generic elements)
 $Z(A, B, C) = \{\vec{0}\}$ iff
 - a) (Dimension 6) one centralizer equals B^3 and the remaining two are different and not equal B^3 , or
 - b) (Dimension 7) two centralizers equal $\mathbb{R}\vec{d} \cap B^3$ and one equals $\mathbb{R}\vec{a} \cap B^3$, but not all are equal, or
 - c) (Dimension 9) all centralizers are different and not equal B^3 .

Now we assume that $(SU(2)^3)_{\text{gen}}$ were trivial. Then

$$(SU(2)^3)_{\text{gen}} \cong (SU(2)^3)_{\text{gen}}/\text{Ad} \times \mathbb{Z}_2 \setminus SU(2),$$

hence

$$\pi_1^h((SU(2)^3)_{\text{gen}}) \cong \pi_1^h((SU(2)^3)_{\text{gen}}/\text{Ad}) \times \pi_1^h(\mathbb{Z}_2 \setminus SU(2)).$$

As we have just seen the codimension of $SU(2)^3 \setminus (SU(2)^3)_{\text{gen}}$ equals 4, i.e., we have $\pi_1^h((SU(2)^3)_{\text{gen}}) = \pi_1^h(SU(2)^3) = \pi_1^h(SU(2))^3 = 1$. On the other hand, $\mathbb{Z}_2 \setminus SU(2) = SO(3)$ and $\pi_1^h(SO(3)) = \mathbb{Z}_2$. Hence,

$$1 \cong \pi_1^h((SU(2)^3)_{\text{gen}}/\text{Ad}) \oplus \mathbb{Z}_2,$$

which obviously is a contradiction. Hence, $(SU(2)^3)_{\text{gen}}$ is nontrivial.

C Other Kinds of Connections

In the literatur there are various kinds of regular connections characterized again by the holonomy group $\mathbf{H}_A$:

1. $\mathcal{A}_{\text{irr}} := \{A \in \mathcal{A} \mid \mathbf{H}_A = \mathbf{G}\}$ (often called irreducible),
2. $\mathcal{A}_{\text{gen}} := \{A \in \mathcal{A} \mid Z(\mathbf{H}_A) = Z(\mathbf{G})\}$ (often called generic),
3. $\mathcal{A}_{\text{alm gen}} := \{A \in \mathcal{A} \mid Z(\mathbf{H}_A) \text{ is discrete}\}$ (we call it almost generic).

Unfortunately, the notations are sometimes diverging. The corresponding sets fulfill $\mathcal{A}_{\text{irr}} \subseteq \mathcal{A}_{\text{gen}} \subseteq \mathcal{A}_{\text{alm gen}} \subseteq \mathcal{A}$ for semi-simple $\mathbf{G}$. If $\mathbf{G}$ is not semi-simple, the center of $\mathbf{G}$ is never discrete [7], hence no centralizer can be discrete. Thus, $\mathcal{A}_{\text{alm gen}}$ would be empty. However, the relation between $\mathcal{A}_{\text{irr}}$ and $\mathcal{A}_{\text{gen}}$ survives for arbitrary $\mathbf{G}$.

As mentioned, e.g., in [5] the inclusions are not always proper. Suppose, e.g., $\mathbf{G} = SU(2)$, then $\mathcal{A}_{\text{irr}} = \mathcal{A}_{\text{alm gen}}$ for simply connected base manifolds M and $\mathcal{A}_{\text{alm gen}} = \mathcal{A}$ for certain M depending on the topology of the bundle $P = P(M, \mathbf{G})$. Moreover, $\mathcal{A}_{\text{gen}} = \mathcal{A}_{\text{alm gen}}$ iff $\mathbf{G}$ is a product of $SU(N_i)$'s only. However, in the case of generalized connections the relation $\overline{\mathcal{A}}_{\text{irr}} \subset \overline{\mathcal{A}}_{\text{gen}}$ is proper for every (at least one-dimensional, but not necessarily semi-simple) Lie group $\mathbf{G}$. This is a simple consequence the following

Proposition C.1 Let M be at least two-dimensional and m be as always some fixed point in M .

For every (abstract) subgroup $H \subseteq \mathbf{G}$ there is a generalized connection whose holonomy group equals H .

Proof Let $\overline{A}_0$ be the trivial connection, i.e. we have $h_{\overline{A}_0}(\gamma) = e_{\mathbf{G}}$ for all $\gamma \in \mathcal{P}$. Furthermore, let m' be some point in M different from m . We choose a set $E := \{\gamma_g\}_{g \in H} \subseteq \mathcal{P}$ of edges connecting m and m' that do not intersect each other (i.e., the only common points of each two edges are their endpoints m and m' , respectively). Such an E exists always because H as a subset of $\mathbf{G}$ has at most the cardinality of $\mathbb{R}$.¹⁹ Obviously the set V_- of all starting points is $\{m\}$, hence finite. By a proposition in [12] there is an $\overline{A} \in \overline{\mathcal{A}}$ with $h_{\overline{A}}(\gamma_g) = g$ for all $g \in H$. In particular, $h_{\overline{A}}(\gamma_g \gamma_{e_{\mathbf{G}}}^{-1}) = g$ for all $g \in H$, hence $H \subseteq \mathbf{H}_{\overline{A}}$. On the other hand, by the definition of $\overline{A}$ (cf. again [12]) and the group property of H , we have $h_{\overline{A}}(\gamma) \in H$ for all $\gamma \in \mathcal{P}$. Hence, $\mathbf{H}_{\overline{A}} \subseteq H$. **qed**

Thus, there are always proper (even countable) subgroups $H \subset \mathbf{G}$ with $Z(H) = Z(\mathbf{G})$ and $H = \mathbf{H}_{\overline{A}}$ for some $\overline{A} \in \overline{\mathcal{A}}$. Up to now, we do not know whether $\overline{\mathcal{A}}_{\text{irr}}$ is open or closed or whatever in $\overline{\mathcal{A}}_{\text{gen}}$. We also do not know whether $\pi : \overline{\mathcal{A}} \longrightarrow \overline{\mathcal{A}}/\overline{\mathcal{G}}$ may be trivial on the irreducible connections. This would be an interesting problem, in particular, because the original paper [27] by Singer on the Gribov ambiguity showed the non-triviality just of the bundle of irreducible (Sobolev) connections.

D Slice Theorem implies Bundle Structure

We are going to prove the following

¹⁹Imagine in some chart (w.l.o.g. equal $\mathbb{R}^{\dim M}$) for instance the set E of all field lines between a positive charge in m and a negative charge in m' . Since there are $\aleph_1$ radial directions starting in m , there are $\aleph_1$ such field lines as well.

Proposition D.1 Let G be a compact topological group and X be a G -space.

If a slice theorem holds on X , then for every closed subgroup $H \subseteq G$ the stratum $X_{=H} := \{x \in X \mid \text{Stab}(x) \sim H\}$ is a locally trivial fibre bundle with typical fibre $H \backslash G$ and structure group $H \backslash N(H)$ acting on $H \backslash G$ by left translation.

Recall that a slice theorem holds on X iff for every $x \in X$ there is a “slice” $S \subseteq X$ with $x \in S$ and open saturation $S \circ G$ and there is an equivariant retraction f of $S \circ G$ onto $x \circ G$ with $f^{-1}(\{x\}) = S$.

For the proof of the proposition above we need

Lemma D.2 Let H be a closed subgroup of the compact group G . Then the group of all equivariant homeomorphisms between $H \backslash G$ and $H \backslash G$ is isomorphic to $H \backslash N(H)$.

Proof For every such $f : H \backslash G \rightarrow H \backslash G$ there is an $a_f \in G$ with $f(Hg) = Ha_f^{-1}g$ for all $g \in G$. [6] Such an a_f has to fulfill $a_f^{-1}Ha_f \subseteq H$, hence has to be in $N(H)$. Conversely, every such a determines a unique f_a of the type above. By $f(H) = Ha_f^{-1}$ the map $f \mapsto a_f$ is unique up to multiplication of a_f by elements of H . Hence $\psi : \text{Homeo}^G(H \backslash G) \rightarrow H \backslash N(H)$, $f \mapsto [a_f^{-1}]_H$, is bijective and by $\psi(f_1 \circ f_2) = \psi(f_1)\psi(f_2)$ even a group isomorphism. **qed**

The proof of Proposition D.1 imitates a proof in [6] that was given there in the case of G being a Lie group. Indeed, this restriction is superfluous because one needs only the validity of a slice theorem.

Proof Proposition D.1

- Since all strata are invariant under G , the validity of a slice theorem on X implies immediately that on the stratum $X_{=[H]}$ considered as a G -space. Hence, we can assume that all points in X have type $[H]$.
- X is a locally trivial fibre bundle.

We construct around every $x \in X$ with $\text{Stab}(x) = H$ a bundle chart. (Obviously there is such an x in every orbit.) For this, let S be a slice through x and $f : S \circ G \rightarrow x \circ G$ be the corresponding equivariant retraction, and let $s \in S$ and $h \in G_s := \{h \in G \mid s \circ h = s\}$. $x = f(s) = f(s \circ h) = f(s) \circ h = x \circ h$ implies $h \in H$, hence $G_s \subseteq H$. By assumption all stabilizers on X are conjugate, we have $G_s = H$. Thus, H acts trivially on S , hence, $S \circ G \cong S \times_H G \cong S \times H \backslash G$ as G -spaces.

Moreover, $S \cong S/H \cong (S \circ G)/G$: Let $c : S \rightarrow (S \circ G)/G$ with $c(s) = [s]$.

- c is surjective by construction.
- c is injective, since $c(s_1) = c(s_2)$ implies $s_1 \circ g = s_2$ for some $g \in G$, hence (using f) $x \circ g = x$, thus $g \in H = G_s$ and finally $s_2 = s_1 \circ g = s_1$.
- c is continuous.
- c is closed, because first for every closed $U \subseteq S$ (by the closedness of $f^{-1}(\{x\}) = S$ in $S \circ G$) U in $S \circ G$, hence (by the compactness of G) also $U \circ G$ in $S \circ G$ is closed, and second $\pi : S \circ G \rightarrow (S \circ G)/G$ is closed.
- c is open, because it is closed and bijective.

Using that identification we get a chart map by the following commutative diagram:

$$\chi_S : \begin{array}{ccc} S \circ G & \xrightarrow{\cong} & S \times H \backslash G \\ \pi \downarrow & \swarrow \text{pr}_1 & \\ S & & \end{array} .$$

- $H \backslash N(H)$ is the structure group of X .

Let χ_S and χ_T be two chart mappings as above. We define for all $x \in S \cap T$ using

$$\chi_T \chi_S^{-1} : (S \cap T) \times H \backslash G \xrightarrow{\cong} (S \cap T) \times H \backslash G$$

$$\searrow \qquad \swarrow$$

$$S \cap T$$

an equivariant homeomorphism

$$\vartheta_x : H \backslash G \longrightarrow H \backslash G \text{ by } \chi_T \chi_S^{-1}(x, Hg) = (x, \vartheta_x(Hg)).$$

According to the proof of Lemma D.2, ϑ_x corresponds via $\vartheta_x(H) = Ha_{\vartheta_x}^{-1}$ to a unique $\rho_T^S(x) := [a_{\vartheta_x}]^{-1} \in H \backslash N(H)$. Hence $\chi_S^{-1}(x, Hg) = \chi_T^{-1}(x, \rho_T^S(x) \circ Hg)$.

We are now left with the proof of the continuity of $\rho_T^S : S \cap T \longrightarrow H \backslash N(H)$.

But, this we get easily from the continuity of $\chi_T \chi_S^{-1}$ by means of

$$\begin{array}{ccccccc} S \cap T & \xrightarrow{\iota} & (S \cap T) \times H \backslash H & \xrightarrow{\chi_T \chi_S^{-1}} & (S \cap T) \times H \backslash N(H) & \xrightarrow{\text{pr}_2} & H \backslash N(H). \\ x & \longmapsto & (x, H) & \longmapsto & (x, Ha_{\vartheta_x}^{-1}) & \longmapsto & \rho_T^S(x) \end{array}$$

qed

E Codimension of Nongeneric Strata

Let $\mathbf{G}$ be a compact Lie group acting smoothly on a manifold M . By $(x_1, \dots, x_k) \circ g := (x_1 \circ g, \dots, x_k \circ g)$ for every $k \in \mathbb{N}_+$ we define an (again smooth) action of $\mathbf{G}$ on M^k . Obviously, the types of this action are again conjugacy classes of closed subgroups of $\mathbf{G}$. Now we have

Proposition E.1 Let $\mathbf{G}$ and M be as above, $\mathbf{H}$ be a closed subgroup of $\mathbf{G}$ and $k \in \mathbb{N}_+$ be arbitrary. Then we have

$$\max_{[\mathbf{K}] < [\mathbf{H}]} \dim(M^k)_{\mathbf{K}} \leq k \max_{[\mathbf{K}] < [\mathbf{H}]} \dim M_{\mathbf{K}}.$$

Proof Let $\vec{x} := (x_1, \dots, x_k) \in (M^k)_{\mathbf{K}}$ for some $[\mathbf{K}] < [\mathbf{H}]$. For some appropriate $g \in \mathbf{G}$ we have $g^{-1} \mathbf{K} g = \text{Stab}(\vec{x}) = \bigcap_i \text{Stab}(x_i) \subseteq \text{Stab}(x_i)$ for all i . Thus, $[\text{Stab}(x_i)] \leq [\mathbf{K}] < [\mathbf{H}]$, hence $x_i \in \bigcup_{[\mathbf{K}_i] \leq [\mathbf{K}]} M_{\mathbf{K}_i}$.

Consequently,

$$(M^k)_{\mathbf{K}} \subseteq \bigtimes_i \left(\bigcup_{[\mathbf{K}_i] \leq [\mathbf{K}]} M_{\mathbf{K}_i} \right) = \bigcup_{[\mathbf{K}_i] \leq [\mathbf{K}]} M_{\mathbf{K}_1} \times \dots \times M_{\mathbf{K}_k}.$$

Since there are only finitely many orbit types on M^k [26], we get

$$\begin{aligned}
\dim(M^k)_{\mathbf{K}} &\leq \max_{[\mathbf{K}_i] \leq [\mathbf{K}]} \dim M_{\mathbf{K}_1} \times \cdots \times M_{\mathbf{K}_k} \\
&= k \max_{[\mathbf{K}'] \leq [\mathbf{K}]} \dim M_{\mathbf{K}'} \\
&\leq k \max_{[\mathbf{K}'] < [\mathbf{H}]} \dim M_{\mathbf{K}'}.
\end{aligned}$$

In particular, we have

$$\max_{[\mathbf{K}] < [\mathbf{H}]} \dim(M^k)_{\mathbf{K}} \leq k \max_{[\mathbf{K}] < [\mathbf{H}]} \dim M_{\mathbf{K}}.$$

qed

Corollary E.2 We have

$$\min_{[\mathbf{K}] < [\mathbf{H}]} \text{codim}_{M^k}(M^k)_{\mathbf{K}} \geq k \min_{[\mathbf{K}] < [\mathbf{H}]} \text{codim}_M M_{\mathbf{K}}.$$

F Proof of Proposition 7.3

First we discuss properties of so-called fundamental systems of connected hyphs, i.e., certain free generating systems for the group of based paths spanned by that hyph. For that purpose, we consider hyphs as abstract graphs. This makes graph-theoretical concepts applicable, like the notion of maximal trees.

- Definition F.1** • Let $v = \{e_1, \dots, e_Y\}$ be a connected hyph with $m \in \mathbf{V}(v)$ and v' be a maximal tree in v . Moreover, let $\phi : [1, n] \longrightarrow [1, Y]$ be an injective function, such that $v' = v \setminus \{e_{\phi(1)}, \dots, e_{\phi(n)}\}$. (This intricate definition is necessary, because v' is to be a hyph again and the hyph property requires a certain ordering of the edges of a hyph.)
- $\alpha \subseteq \mathcal{HG}$ is called **weak v' -fundamental system for v** iff for every $i = 1, \dots, n$ the path α_i can be expressed as a product of three paths, whereas the first and the third path are contained in $\mathcal{P}_{\{e_{\phi(1)}, \dots, e_{\phi(i-1)}\} \cup v'}$ and the second path equals the edge $e_{\phi(i)}$.
- The edge $e_{\phi(i)}$ is called **free** edge of α_i .
- $\alpha \subseteq \mathcal{HG}$ is called **weak fundamental system** iff there are a connected hyph v and a maximal tree v' in v , such that α is a weak v' -fundamental system for v .

Here, $\mathcal{P}_\gamma$ denotes the subgroupoid of $\mathcal{P}$ generated by $\gamma \subseteq \mathcal{P}$. Analogously, $\mathcal{HG}_\beta$ is defined. We have obviously

Lemma F.1 Every connected hyph possesses a weak fundamental system.

The basic properties of weak fundamental systems are summarized in

Proposition F.2 Let v be a connected hyph with $m \in \mathbf{V}(v)$, and let α be a weak fundamental system of v . Then the following holds:

1. $\mathcal{P}_\alpha$ is freely generated by α and equals $\mathcal{HG}_v$;
2. $\pi_\alpha \mu_0 = \mu_{\text{Haar}}^\# \alpha$;
3. $\pi_\alpha : \overline{\mathcal{A}} \longrightarrow \mathbf{G}^\# \alpha$ is surjective.

Consequently, every weak fundamental system of a connected hyph is a weak hyph.

Proof By assumption there is a maximal tree v' in $v = \{e_1, \dots, e_Y\}$, such that α is a v' -fundamental system of v . In order to avoid more complicated expressions, we simply assume $v' = \{e_{n+1}, \dots, e_Y\}$.

1. • Obviously $\mathcal{P}_\alpha \subseteq \mathcal{H}\mathcal{G}_v$.

• We show $\mathcal{H}\mathcal{G}_v \subseteq \mathcal{P}_\alpha$ inductively w.r.t. $n = \#\alpha = \#v - \#v'$.

For $n = 0$ the statement is trivial. Now, let $n > 0$ and $\gamma \in \mathcal{H}\mathcal{G}_v$, i.e. $\gamma = \gamma_1 e_n^{\eta_1} \gamma_2 e_n^{\eta_2} \dots e_n^{\eta_q} \gamma_{q+1}$ with $\gamma_j \in \mathcal{P}_{\tilde{v}}$ and $\eta_j = \pm 1$ for all j . Here $\tilde{v} := v \setminus \{e_n\}$. Let δ_{+1} and δ_{-1} be those paths in $\mathcal{P}_{\tilde{v}}$ that fulfill $\alpha_n = \delta_{-1} e_n \delta_{+1}$. Hence,

$$\gamma = \underbrace{\gamma_1 \delta_{-\eta_1}^{-1}}_{\in \mathcal{H}\mathcal{G}_{\tilde{v}}} \alpha_n^{\eta_1} \underbrace{\delta_{-\eta_1}^{-1} \gamma_2 \delta_{-\eta_2}^{-1}}_{\in \mathcal{H}\mathcal{G}_{\tilde{v}}} \alpha_n^{\eta_2} \delta_{-\eta_2}^{-1} \dots \delta_{-\eta_q}^{-1} \alpha_n^{\eta_q} \underbrace{\delta_{-\eta_q}^{-1} \gamma_{q+1}}_{\in \mathcal{H}\mathcal{G}_{\tilde{v}}}. \quad (10)$$

By $e_n \notin v'$, also v' is a maximal tree for $\tilde{v}$ and, in particular, $\tilde{v}$ is connected. Now, $\alpha \setminus \{\alpha_n\}$ is a weak v' -fundamental system for $\tilde{v}$. Due to $\#\tilde{v} - \#v' = \#v - \#v' - 1 = n - 1$ we have by the induction hypothesis $\mathcal{H}\mathcal{G}_{\tilde{v}} = \mathcal{P}_{\alpha \setminus \{\alpha_n\}}$. Equation (10) implies $\gamma \in \mathcal{P}_\alpha$.

• Consequently, α is a generating system of the free group $\mathcal{H}\mathcal{G}_v$, whose rank equals $\#v - \#v'$, hence $\#\alpha$. Thus, α is free. [22]

2. We have

$$\begin{aligned} \pi_\alpha^v : \quad \mathbf{G}^Y &\longrightarrow \mathbf{G}^n, \\ (g_1, \dots, g_Y) &\longmapsto (\dots g_1 \dots, \dots, \dots g_n \dots) \end{aligned}$$

where the $\dots$ in $\dots g_i \dots$ denote a product of some g_j or g_j^{-1} with $j > n$ or $j < i$. Now, we get for all $f \in C(\mathbf{G}^n)$ using successively the structure of $\dots g_i \dots$ and the translation invariance and the normalization of the Haar measure

$$\begin{aligned} &\int_{\mathbf{G}^Y} (\pi_\alpha^v)^* f \, d\mu_{\text{Haar}}^Y \\ &= \int_{\mathbf{G}^Y} f(\pi_\alpha^v(g_1, \dots, g_Y)) \, d\mu_{\text{Haar},1} \dots d\mu_{\text{Haar},Y} \\ &= \int_{\mathbf{G}^Y} f(\dots g_1 \dots, \dots, \dots g_{n-1} \dots, \dots g_n \dots) \, d\mu_{\text{Haar},1} \dots d\mu_{\text{Haar},Y} \\ &= \int_{\mathbf{G}^Y} f(\dots g_1 \dots, \dots, \dots g_{n-1} \dots, g_n) \, d\mu_{\text{Haar},1} \dots d\mu_{\text{Haar},Y} \\ &\vdots \\ &= \int_{\mathbf{G}^n} f(g_1, \dots, g_n) \, d\mu_{\text{Haar},1} \dots d\mu_{\text{Haar},n} \\ &= \int_{\mathbf{G}^n} f \, d\mu_{\text{Haar}}^n. \end{aligned}$$

Since π_v projects the induced Haar measure onto the Haar measure [12], we have $\pi_{\alpha*} \mu_0 = (\pi_\alpha^v)_* (\pi_{v*} \mu_0) = (\pi_\alpha^v)_* \mu_{\text{Haar}}^Y = \mu_{\text{Haar}}^n$.

3. Let $(g_1, \dots, g_n) \in \mathbf{G}^n$. By assumption we can express every e_i , $i \leq n$, as a product of α_i with appropriate paths in $\mathcal{P}_{\{e_1, \dots, e_{i-1}\} \cup v'}$. Now, we choose $\delta_{i,\pm} \in \mathcal{P}_{v'}$, such that $\delta_{i,-} e_i \delta_{i,+}$ is a path in $\mathcal{H}\mathcal{G}$. But, then $\delta_{i,-} e_i \delta_{i,+}$ equals a product of a closed path in $\mathcal{P}_{\{e_1, \dots, e_{i-1}\} \cup v'}$, the path α_i and a further closed path $\mathcal{P}_{\{e_1, \dots, e_{i-1}\} \cup v'}$. By the first step $\mathcal{H}\mathcal{G}_{\{e_1, \dots, e_{i-1}\} \cup v'} = \mathcal{P}_{\{\alpha_1, \dots, \alpha_{i-1}\}}$. Hence, $\delta_{i,-} e_i \delta_{i,+} = \prod_{k_i}^{K_i} \alpha_{k(k_i,i)}^{\pm 1} \alpha_i \prod_{l_i}^{L_i} \alpha_{l(l_i,i)}^{\pm 1}$ for some functions k and l , that fulfill always $k(k_i, i) < i$ and $l(l_i, i) < i$.

Since π_v is surjective for every hyph [12], there is an $\bar{A} \in \bar{\mathcal{A}}$, such that $h_{\bar{A}}(e_i) = e_{\mathbf{G}}$ for all $i > n$ and $h_{\bar{A}}(e_i) = h_{\bar{A}}(\delta_{i,-})^{-1} \left(\prod_{k_i}^{K_i} g_{k(k_i,i)}^{\pm 1} \right) g_i \left(\prod_{l_i}^{L_i} g_{l(l_i,i)}^{\pm 1} \right) h_{\bar{A}}(\delta_{i,+})^{-1}$ for all $i \leq n$ (defined inductively, since $\delta_{i,\pm}$ may run through $e_{i'}$ with $i' < i$ or $i' > n$). By construction we have $h_{\bar{A}}(\alpha_i) = g_i$ for all $i = 1, \dots, n$. **qed**

Finally, we have

Proof Proposition 7.3

First we choose a $\beta \subseteq \mathcal{HG}$ with $Z(h_{\bar{A}}(\beta)) = Z(\mathbf{H}_{\bar{A}})$. Since β is obviously connected, there is a connected hyph v , such that every path in β can be expressed by paths in v . (The existence of a hyph is proven in [12], the connectedness is a simple consequence [14].) Lemma F.1 guarantees the existence of a weak fundamental system $\alpha \subseteq \mathcal{HG}$ for v . By Proposition F.2, α is a weak hyph. Since every $\beta \in \mathcal{HG}$ is a closed path in v by construction, it can be written as a product of paths in α (and their inverses). Hence, $h_{\bar{A}}(\beta)$ is a product of $h_{\bar{A}}(\alpha_i)$ and their inverses. Now, let $g \in Z(h_{\bar{A}}(\alpha))$. Then g commutes with all finite products of $h_{\bar{A}}(\alpha_i)$ and their inverses as well; thus, in particular, $g \in Z(h_{\bar{A}}(\beta))$. This implies $Z(\mathbf{H}_{\bar{A}}) \subseteq Z(h_{\bar{A}}(\alpha)) \subseteq \bigcap_{\beta \in \beta} Z(h_{\bar{A}}(\beta)) = Z(h_{\bar{A}}(\beta)) = Z(\mathbf{H}_{\bar{A}})$, hence $Z(h_{\bar{A}}(\alpha)) = Z(\mathbf{H}_{\bar{A}})$. **qed**

G Homeomorphy Criterion

Proposition G.1 Let X be a topological space, Y be a Hausdorff space and $f : X \longrightarrow Y$ be a bijective and continuous mapping. If every point in Y has a compact neighbourhood whose preimage is compact again, then f is a homeomorphism.

Proof Let $x \in X$. By assumption there is a compact neighbourhood $W \subseteq Y$ of $f(x)$ such that $V := f^{-1}(W)$ is compact again. By continuity of f , V is a neighbourhood of x . Hence, $f|_V : V \longrightarrow W$ is a bijective and continuous mapping of a compact space into a Hausdorff space, hence a homeomorphism.

Now we show that f^{-1} is continuous in $f(x)$. For this, let U be an open neighbourhood of x in X and $W_0 \subseteq W$ be an open neighbourhood of $f(x)$ in Y . If one sets $V_0 := f^{-1}(W_0)$, then $U \cap V_0$ is an open neighbourhood of x in X , hence in V as well. Consequently, $f|_V(U \cap V_0) = f(U \cap V_0)$ is open w.r.t. $f(V) = W$. By $f(V_0) = W_0$ and the bijectivity of f we have $f(U) \cap W_0 = f(U) \cap f(V_0) = f(U \cap V_0) \subseteq W_0$. But, $f(U) \cap W_0$ is open in W , hence in W_0 as well and thus (by the openness of W_0 in Y) in Y , too. Hence, $f(U) \supseteq f(U) \cap W_0 \ni f(x)$ is a neighbourhood of $f(x)$ in Y . Since this is true for all open neighbourhoods U of x , f^{-1} is continuous. **qed**
